Abridged List of Publications published by the Authority of the Meteorological Committee

A complete list will be forwarded on application to the Director, Meteorological Office, Air Ministry, London, W.C.2.

Publications may be ordered (unless otherwise indicated) directly from the Sale Offices of
HIS MAJESTY'S STATIONERY OFFICE.

MANCHESTER— York Street.
LONDON— Adastral House, Kingsway, W.C.2.
EDINBURGH— 120, George Street.
CARDIFF— 1, St. Andrew's Crescent.
BELFAST— 15, Donegall Square West.

Or through any bookseller.

The list is arranged under the headings:—

1. HANDBOOKS, TEXTBOOKS, TABLES
2. JOURNALS
3. PUBLICATIONS OF DATA (CURRENT PERIODICAL ISSUES)
4. PUBLICATIONS OF NORMALS OR AVERAGES
5. CHARTS OF MARINE METEOROLOGY (*see complete list*)
6. PUBLICATIONS OF RESEARCHES
7. ANNUAL REPORTS OF THE METEOROLOGICAL OFFICE
8. ANNUAL REPORTS OF THE ADVISORY COMMITTEE ON ATMOSPHERIC POLLUTION (*see complete list*)
9. REPORTS OF INTERNATIONAL METEOROLOGICAL MEETINGS

1. HANDBOOKS, TEXTBOOKS, TABLES

Barometer Manual for the use of Seamen. A Textbook of Marine Meteorology. 10th edition, 1925. (No. 61.) (8vo.) 1s. 6d. Postage 2½d.

Codes of Signals adopted and recommended by the International Meteorological Committee, 1910–13, for Storm Warnings, together with a list of the Maritime Weather Signals at present in use in the various Countries of the Globe. 4th edition, 1913. (No. 206.) (8vo.) 4d. Postage 1d.

Computer's Handbook. Issued in Sections. (No. 223.) (8vo.):—
Introduction. C.G.S. Units of Measurement in Meteorology, with their abbreviations and their equivalents. 1921. 3s. 6d. Postage 1d.
Section II, Subsection 1. The Computation of Wind Components from Observations of Pilot Balloons and Shell Bursts. 1920. 2s. Postage 1d.
Section V, Subsection 3. A Collection of Correlation Co-efficients from Meteorological Papers and a Note on the Partial Correlation Co-efficient. 1919. 4s. Postage 1½d.
(*The remaining sections are out of print.*)

Decode for use with International Code for Wireless Weather Messages from Ships, adopted by the International Meteorological Conference, Copenhagen, September, 1929. 2nd edition, 1931. (No. 329.) (8vo.) 3d. Postage ½d.

Dines Balloon Meteorograph and the Method of using it. By L. H. G. Dines, M.A. (No. 321. 1929.) (8vo.) 2s. Postage 2d.

Hygrometric Tables for the Computation of Relative Humidity, Vapour Pressure and Dew Point from Readings of Dry and Wet Bulb Thermometers exposed in Stevenson Screens. 2nd edition, 1927. (No. 265.) (8vo.) 2s. Postage 1d.

International Codex of Resolutions adopted at Congresses, Conferences and at Meetings of the Permanent International Meteorological Committee. 1872–1907. (No. 200. 1909.) (8vo.) 1s. 3d. Postage 1½d.

Marine Observer's Handbook. 5th edition, 1930. (No. 218.) (8vo.) 2s. 6d. Postage 4d.

Meteorological Corrections for the use of Gunners. Notes on. By D. Brunt, M.A., and J. Durward, M.A. (No. 241. 1921.) (8vo.) 3d. Postage ½d.

Meteorological Glossary (continuation of the **Weather Map,** q. v.). 2nd edition. Entirely rewritten. 1930. (No. 225ii.) (8vo.) 4s. 6d. Postage 4d.

Meteorological Observer's Handbook. Approved for the use of Meteorological Observers by the Meteorological Office and the Royal Meteorological Society. 1926 edition. (No. 191.) (8vo.) 5s. Postage 3½d.
Supplement No. 1. Instructions for Meteorological Telegraphy. 2nd edition. 1930. (No. 191/1.) (8vo.) 2s. 6d. Postage 1½d.
Supplement No. 2. Instructions to Observers at Auxiliary Climatological Stations. (No. 191/2. 1927.) (8vo.) 3d. Postage ½d.
Supplement No. 3. Instructions to Observers at Normal Climatological Stations. (No. 191/3. 1927.) (8vo.) 4d. Postage 1d.

1. HANDBOOKS, TEXTBOOKS, TABLES—*contd.*

Meteorological Observer's Handbook—*contd.*

Supplement No. 4. Instructions to Observers at Climatological Stations at Health Resorts. (No. 191/4. 1927.) (8vo.) 4d. Postage 1d.

Meteorological Reports issued by Wireless Telegraphy in Great Britain and the Countries of Europe and North Africa. 8th edition, 1931. (No. 252.) (8vo.) 3s. Postage 3d. (*Supplements issued as necessary and priced separately.*)

Meteorology, Elementary. A Short Course in. By W. H. Pick, B.Sc., F.C.P. 3rd edition, 1930. (No. 247.) (8vo.) 2s. 6d. Postage 3d.

Meteorology in Relation to Air Pilotage. Reprint of Chapter XI of the "Manual of Air Pilotage." (No. 327. 1930.) (Demy 8vo.) 6d. Postage 1d.

New International Code for Meteorological Messages. Reprint of Section IV of No. 252. (No. 253. 1922.) (8vo.) 4d. Postage ½d.

Observer's Primer, being Short Instructions in the Method of Taking and Reporting Readings of Temperature and Rainfall, specially prepared for Meteorological Observers in the British Colonies. 2nd edition. 1930. (No. 266.) (8vo.) 3d. Postage ½d.

Seaman's Handbook of Meteorology. A companion to the Barometer Manual for the use of Seamen. 3rd edition, 1917. (No. 215.) (8vo.) (*Out of print.*)

Tables for the Reduction of Meteorological Observations. Published by the Indian Meteorological Department. Includes Tables for finding the Absolute and Relative Humidities from Readings of Wet and Dry Bulb Thermometers. (4to.) 2s. Postage 5d.

Tropical Africa. Hints to Meteorological Observers in. With Instructions for taking Observations and Notes on Methods of recording Lake Levels. 2nd edition. Revised 1907. (No. 162.) (8vo.) 9d. Postage 1d.

Weather Forecasting for Seamen, in the Eastern North Atlantic and Home Waters. By Commander L. A. Brooke Smith, R.D., R.N.R. (No. 246. 1921.) (8vo.) 6d. Postage 1d.

Weather Forecasts Transmitted by Telegraphy or Radio-Telegraphy. Forecast Code for the Abbreviation of. (No. 244. 1922.) (8vo.) (*Not on sale.*)

Weather Map. An introduction to Modern Meteorology. 2nd edition. Entirely rewritten. 1930. (No. 225i.) (8vo.) (*See also* **Meteorological Glossary,** *in continuation of the* Weather Map.) 3s. Postage 2d.

Weather of the British Coasts. (No. 230. 1918.) (8vo.) (*Out of print.*)

Wireless and Weather—An Aid to Navigation. By Captain L. A. Brooke Smith, R.D., R.N.R. Reprinted from the **Marine Observer, Vol. IV,** with Appendices. (No. 297. 1928.) (4to.) 5s. Postage 6d.

PREFACE.

Up to the end of 1921, the serial statistical publications of the Meteorological Office were grouped together as though they were parts of one comprehensive book. This book, which was entitled "The British Meteorological and Magnetic Year Book," consisted of :—

Part I	The Weekly Weather Report.
Part II	The Monthly Weather Report.
Part III, Section I	Daily Readings at Meteorological stations of the First and Second Orders.
Section II	Geophysical Journal, Daily Values of Meteorological and Geophysical Elements.
Part IV, Section I	Hourly Values from Autographic Records. Meteorological Section.
Section II	Hourly Values from Autographic Records. Geophysical Section.
Part V	Réseau Mondial.

The data for the year 1922 and subsequent years are found in the following publications :—

New Publication from 1922.	Corresponding parts of the British Meteorological and Magnetic Year Book until the end of 1921.
The Weekly Weather Report	Part I.
The Monthly Weather Report	Part II.
The Observatories' Year Book	Part III, Section II. Part IV, Section I.* Part IV, Section II.
The Réseau Mondial	Part V.

It will be noticed that Part III, Section I, of the old publication is not included in the new issues. This part contained "Daily Readings at Meteorological Stations of the First and Second Orders," and it has been decided that as the Observatories' Year Book contains daily values of the meteorological elements for the principal first order stations and the Daily Weather Report contains daily values for these and about 40 other stations, it is not necessary to revive the issue of this section, which ceased with the data for 1921.

The present volume is the eighth issue of the Observatories' Year Book. It contains geophysical data for Lerwick, Eskdalemuir, Cahirciveen and Richmond, meteorological data for Aberdeen, Eskdalemuir, Cahirciveen and Richmond, and in addition an aerological section giving the results of soundings of the upper atmosphere by means of registering balloons.

The only addition to this volume is a table of daily readings of temperature in the ground as recorded at Eskdalemuir Observatory.

The table of mean annual values of magnetic data for observatories of the globe has been contributed by the Astronomer-Royal. It will be found in the Eskdalemuir section.

---

*Part IV., Section I., Hourly Values from Autographic Records, Meteorological Section, was discontinued after the data for 1913 had been published. The hourly values for the years 1914 to 1921 are, however, available in manuscript.

Note.—The height given is that of the site of the rain-gauge. The heights of other meteorological instruments are shown in the appropriate Tables.

† The site of the rain-gauge was altered on 1st June 1928.

NORMAL VALUES AND MONTHLY SUMMARIES.

Monthly and annual normals of pressure, dry bulb temperature, and rainfall for each hour of the day and for the period of 45 years, 1871–1915, are published for the observatories, Aberdeen, Cahirciveen, Richmond and Falmouth in *Hourly Values from Autographic Records*, 1917 (Part IV. of the British Meteorological and Magnetic Year Book, 1917), and in previous volumes of that series. Corresponding normals of wind-speed and sunshine are published there for the same observatories and for the period of 35 years, 1881–1915; while corresponding normals of relative humidity are also published there for the period of 30 years, 1886–1915.

For Eskdalemuir the same publication gives hourly averages for the months and for the year, referred to the period 1911–1915.

Summaries giving additional mean values and frequencies of occurrence of various meteorological phenomena will be found for all the observatories in *The Monthly Weather Report* and its Annual Summary. The latter also contains special summaries of the tabulations of the anemographs.

Monthly normal values of maximum, minimum and mean temperature, rainfall and sunshine for the period 1881–1915 are published in the *Book of Normals, Section I* for Aberdeen, Cahirciveen, Richmond and Falmouth. *Section IV* of the same publication gives information regarding the range of variation of temperature and rainfall at the same observatories, and monthly frequencies of the normal numbers of days of hail, thunder, snow, snow-lying and ground frost. *Section VI* of the *Book of Normals* gives tables and isopleth diagrams showing the normal diurnal and seasonal variation of relative humidity at all the observatories for which data of relative humidity are included in this volume.

GENERAL INTRODUCTION TO THE METEOROLOGICAL TABLES.

The elements dealt with in the following meteorological tables for the Observatories at Aberdeen, Eskdalemuir, Cahirciveen and Richmond are :—barometric pressure, air temperature, humidity, rainfall, sunshine, wind speed and direction, minimum night temperature on the grass, cloud, visibility and weather, and in some cases temperature in the ground, solar radiation and level of underground water.

The positions of the Observatories and the heights of the sites are given on p. 8.

Notes on the Instruments and Tabulation of the Records.

A detailed description of the barograph, thermograph, and Beckley raingauge used for obtaining the records of pressure, temperature, humidity, and rainfall is given in the *Reports* of the Meteorological Office for the years 1867 and 1869; for a description of other instruments in use reference may be made to the *Meteorological Observer's Handbook* and to the article on Meteorological Instruments in the *Dictionary of Applied Physics*, Vol. III. The following notes are supplementary and are given partly for reference and partly as containing information necessary for the interpretation of the tables.

Barometer.—The record of barometric pressure is obtained photographically from a mercurial barometer.

A beam of light is passed through the space between the surface of the column of mercury and the top of the tube, and, after passing through a diaphragm which reduces the width of the beam of light to a very narrow sharp line, is focussed upon a sheet of sensitized paper (ordinary "bromide" paper is employed) carried upon a cylinder which is rotated by clockwork and makes one revolution about its vertical axis in rather more than 48 hours.

The barogram is therefore a continuous photograph of this narrow vertical line, and appears as a horizontal ribbon, the depth of which is constantly varying with the rise or fall of the mercury in the tube of the barometer.

The expansion of a zinc rod is utilised to compensate for the effect of temperature upon the height of the barometric column; the arrangement produces mechanically a lengthening of the beam of light at its upper end as it becomes shortened at its lower extremity by the expansion of the mercury in the tube. A time-scale is recorded upon the barogram by means of a shutter actuated by the clock. This shutter cuts off the light for the space of four minutes every two hours, thus producing interruptions which appear as narrow white spaces on the record corresponding with known points of time. Until 1918 these time-breaks occurred at the even hours, 2h, 4h, 6h, etc., but it was found that when the edge of the record was not critically sharp owing to various causes, a systematic error was introduced when measuring the records, whereby the values at the even hours were slightly in excess of those at the odd hours where no time-break existed. From 1918 onwards the clock was so arranged that the time-breaks should occur half an hour between the even hours; by this means both even and odd hour-values are measured at points on the trace which are unaffected by any systematic difference.

Control readings of a standard barometer are taken three times a day by different observers. The control readings are first corrected for index error, temperature and gravity, and then compared with the corresponding readings of the barogram. The differences between the control readings and the corresponding tabulated values

are then found and a correction derived therefrom is applied to all the tabulated values. This correction, known as the "residual correction," is so applied as to run smoothly throughout the whole length of each record—a period of 48 hours—and alterations in the amount of the correction occur, where necessary, in steps not exceeding 0·1 millibar.*

The scale value of the barograms is found from a comparison of a series of such standard and curve readings. The indications of a curve are converted into numerical values by measuring the ordinates with a tabulating instrument, graduated according to the ascertained scale value.

Thermometers.—The air temperature and humidity data at each Observatory are derived from records obtained photographically from two mercurial thermometers. One thermometer is used as a dry bulb and the other as a wet bulb thermometer.

Each thermometer has a large cylindrical bulb four inches long and a very long stem. The latter is bent twice at right angles to enable the bulb to be exposed outside the building in a louvred screen attached to the north wall of the Observatory.† The column of mercury in the vertical portion of the stem inside the building is broken at a convenient point by a small air space which moves up or down the stem with rise or fall of temperature. The record is obtained by passing a reflected beam of light through the air space and photographing its image upon a moving sheet of "bromide" paper in the same manner as described in the case of the barometer. A base line is traced on the paper by a pencil of light passing through a small aperture in the brass frame carrying the recording thermometer. The time-scale is automatically recorded upon the curves, a time-break occurring half an hour before each even hour.

Two large standard thermometers with very open scales graduated in degrees absolute and having bulbs similar to those of the thermograph are mounted in the screen side by side and close to the thermograph bulbs. One of the thermometers is arranged as a dry bulb, the other as a wet bulb. Control readings of these thermometers are made three times a day for comparison with the corresponding readings obtained from the thermograms.

The scale-value of the curves is found by a comparison of the readings of the standard thermometers, corrected for any errors they may have, with the corresponding measurements of the curves. The curves are measured by means of a plate of glass ruled with lines corresponding with the ascertained scale-value of the record, both for temperature and for time. The scale is graduated so as to read degrees vertically and hours horizontally.

Two alternative methods of reading the curves have been adopted.

(*a*) At Richmond the scale is set by the base-line and after hourly readings have been obtained for the whole record comparisons are made with the control readings. The residual correction so determined (normally the same for the whole record of 48 hours) is applied to the tabulations.

(*b*) At Aberdeen, Eskdalemuir and Cahirciveen, the practice is to adjust the glass scale so that the readings at the control hours on the trace are made to show general agreement with the corresponding eye-readings of the standard thermometers. The temperature equivalent of any part of the curve can then be read off. The base-line photographed on the record serves as a useful check.

---

* At Cahirciveen and Richmond the rule is to apply the same correction for the whole chart.

† At Eskdalemuir the screen stands in the open.

Rainfall.—This element is recorded by a Beckley self-registering raingauge, in which the rain as it falls is collected in a receiver supported on a float in a vessel of mercury. As the rain passes into the receiver, the float gradually sinks, carrying with it a pen which records its position upon a paper stretched upon a clock-driven cylinder. The displacement of the mercury by the float is arranged so as to give a uniform scale throughout. When five millimetres (two-tenths of an inch) of rain have entered the receiver a siphon comes into action, and, by discharging its contents, causes the float to rise till the pen is brought back to the zero line, from which the record begins again.

The collecting funnel of the Beckley raingauge has an area of approximately 100 square inches. Each gauge stands on level ground and its distance from every other object is greater than twice the height of the object. The height of the rim of the Beckley raingauge above the surface of the surrounding ground varies from 0·4 m. to 0·6 m. at the different observatories. Details are given at the head of the tables of hourly values. A check gauge with funnel 8 inches in diameter is installed near by.

The records obtained from the Beckley self-registering raingauge are, if necessary, subjected to a proportional correction whereby they are brought into agreement with the amount of rainfall as recorded by the check raingauge which is read twice daily at 7h. and 18h.

Sunshine.—The record of sunshine is obtained from a Campbell-Stokes recorder, in which instrument the sun's rays are focussed through a 4-inch spherical lens of crown glass upon a strip of blue card, which is scorched, or burned right through, according to the intensity of the sun's rays. Three different patterns of card are used at different seasons of the year. The cards are exposed in a metal bowl, and the focussed image of the sun leaves its mark behind it as it travels along the surface of the card with the apparent motion of the sun through the heavens. The intensity of the burn is not measured, but the record is regarded as that of " bright " sunshine whenever the card has been distinctly scorched. When measuring the duration of sunshine which is represented by intermittent burns, an allowance is made for the extension of the trace by the charring of the card.

Wind - Speed and Direction.—The hourly values of wind-speed and direction which appear in this volume are derived from the records of Dines tube anemographs. These instruments record the speed of the wind and its direction directly as functions of the time. For volumes previous to that of 1926 the hourly values of wind-speed and direction were derived from the records of Robinson Cup Anemographs, except at Eskdalemuir, where the records of tube-anemographs have always been used for the purpose of hourly values. Particulars of the exposure of the tube-anemographs at the several observatories will be found in the introductions to the data for each observatory. A description of the tube anemograph will be found in the *Meteorological Observer's Handbook.*

In consequence of these changes the values of wind-speed published for Aberdeen, Cahirciveen and Richmond for 1926 and later years are not directly comparable with those published in earlier years. The matter was briefly discussed in the General Introduction to the *Year Book* for 1926. The following table gives, for the various wind directions, the mean values of wind-speed recorded by the tube anemographs, expressed as percentages of the corresponding values recorded by the cup anemographs :—

Average values of the quantity 100 $\times \frac{\text{Speed by tube anemograph}}{\text{Speed by cup anemograph}}$

at the three observatories, arranged according to the direction of the wind.

North = 360°, East = 90°, South = 180°, West = 270°.

Minimum Night Temperature on the Grass.—This is the temperature determined by a minimum thermometer exposed freely over the surface of the grass. The stem of the thermometer is enclosed in an outer glass jacket, but the spirit bulb is freely exposed to the air. The thermometer is supported on two small Y-shaped pieces of wood so that it lies horizontally, with its bulb about one or two inches above the ground which is covered with short grass. When snow has fallen the thermometer is supported so as to lie just above the surface of the fallen snow, but not touching it.

The thermometer is laid out at 18h. each day, having been kept in an upright position, bulb downwards, inside the Stevenson Screen during the daytime, so that any spirit that may have condensed in the upper part of the stem may be able to run down and join the main spirit column.

Notes on the Tables.

General.—Interpolated values are printed within brackets, ( ). Maximum and minimum values are printed in heavy type.

Standard of Time.—The observations are referred to *Greenwich Mean Time* except as regards sunshine, for which element *local apparent time* is used.

Units.—In accordance with the practice introduced in 1911, as a consequence of certain resolutions of the Gassiot Committee of the Royal Society, the values in the tables are expressed throughout in units based upon the C.G.S. System: tables for conversion to other units are given in the *British Meteorological and Magnetic Year Book* (*Part IV*) for 1913 and are also to be found in the *Computer's Handbook.*

Daily Mean Values.—The daily means of pressure, temperature, relative humidity and wind speed are obtained by adding half the sum of the values for the initial and final midnights to the sum of the 23 intermediate hourly values and dividing by 24.

In the preparation of the tables of diurnal inequalities for individual months and for the year, it is assumed that the difference of value between the means for the initial and final midnights, which may be termed, so far as the hourly variations are concerned, the non-cyclic variation, is equally distributed over the whole 24-hour period. Thus, in a table of diurnal inequalities the entry d_n for the hour n is given by

$$d_n = x_n - \bar{x} - (n - 12)\ (x_{24} - x_0)/24,$$

x_n being the value of the element at hour n and $\bar{x}$ the mean for 24 hours.

Annual Values.—The mean values or totals for the whole year (given either in separate tables or at the end of the corresponding monthly tables), are computed as the means or sums of 365, in leap year 366, daily values.* The annual values of pressure at sea level are computed from the annual means at station level and the annual means of air temperature; the annual values of vapour pressure are derived from the annual means of air temperature and relative humidity.

Atmospheric Pressure.—All pressures recorded in this volume are expressed in *millibars*, one millibar being equal to 1000 dynes per square centimetre. The following are the values of physical constants used in evaluating the data :—

Density of Mercury = 13·5955 grams per cc. at 0°C.
Intensity of Gravity at Sea Level (Lat. 45°) = 980·617 centimetres per second per second.
1 inch = 25·4000 millimetres.

Hence a pressure of 1000 millibars corresponds with a reading of 750·076 millimetres on a mercury barometer at temperature 0°C. in Lat. 45° and is equivalent to 29·5306 inches under standard conditions of temperature (mercury at freezing point, scale at 62° F.) in Lat. 45°.

The true pressure in millibars can only be obtained from the reading of a barometer after the latter has been suitably corrected for (*a*) index error, (*b*) temperature, and (*c*) gravity.

These corrections have been applied to the barometer readings in obtaining the pressure values published in this volume. The corrections for index error (including those for capillarity) are given in the certificates issued by the Kew Observatory or the National Physical Laboratory in respect of the standard barometers at each observatory. The corrections for temperature are equivalent to those published in the *International Meteorological Tables* (Gauthier-Villars, Paris, 1890). The correction for the variation of gravity from its standard value at sea level in latitude 45°, quoted above, is in accordance with the formula adopted in the *International Tables*, viz. :—

$$g_{z,\lambda}/g_{0,45^\circ} = (1 - 0{\cdot}00259 \cos 2\lambda)\ (1 - 5z/4E)$$

where z = height of the station above M.S.L.
E = earth's radius, both expressed in the same units,
and λ = latitude of station.

Except at Eskdalemuir, the correction for the variation of gravity with height, contained in the second factor of the above equation, is insignificant.

* At Eskdalemuir the annual values for the years 1922 to 1926 were computed as the means or sums of 12 monthly values.

Unless otherwise stated, all pressure values refer to the level of the observatory, as given in the headings of the tables. The reduction to sea-level, wherever made, is effected by tables drawn up for each observatory in accordance with the following scheme :—

If p is pressure at station level, and P is pressure at sea-level, the correction required to reduce p to sea-level is $P-p$ where

$$\log_e (P/p) = \bar{g}z\,(1-3\,\bar{w}/8p)/K\bar{T}.$$

z = height of station in centimetres.

e = base of Napierian logarithms.

K = gas constant for dry air = $10^9/348{\cdot}4$ C.G.S. units.*

$\bar{T}$ = mean absolute temperature of the air column between station level and mean sea-level.

$\bar{w}$ = mean value of water vapour pressure in the column.

$\bar{g}$ = mean value of the acceleration of gravity in the air column. Even at Eskdalemuir, the highest station, the effect on the correction of the variation of gravity with height is, in this case, negligible, so that

$$\bar{g} = 980{\cdot}617\,(1-0{\cdot}00259\cos 2\lambda).$$

The factor $(1-3\,\bar{w}/8p)$ in the above formula is practically unity except at Eskdalemuir. Its value for that observatory is discussed in the Introduction to the Eskdalemuir section.

In the same way, the value of $\bar{T}$ at each observatory differs inappreciably from the value of air temperature at the observatory, except in the case of Eskdalemuir (*see* Introduction to Eskdalemuir section for details).

Hence at all observatories except Eskdalemuir, no corrections are applied for the effects of water vapour, or of change of air temperature in the column of air between the station and sea level.

The scheme for correcting barometer readings outlined above was introduced for Eskdalemuir at the beginning of 1927. For the other observatories, it has come into effect as from 1st January, 1928. The effects of the introduction of the scheme on the tabulated values are briefly referred to in the several introductions to the individual sections. Only at Eskdalemuir are they at all appreciable.

The tables contain values of pressure at exact hours obtained from the photographic barograms in the manner described on p. 9 ; also daily, monthly and annual means of hourly values, together with the monthly and annual means of diurnal inequalities. Monthly and annual means of the hourly values after reduction to mean sea level are also given.

There is also a table showing the daily extremes of pressure, *i.e.*, the maximum and minimum values recorded during each day.

Temperature.—The scale on which temperatures are recorded is such that the freezing point of water under atmospheric pressure is 273a precisely. Other temperatures differ by 273·0 from readings on the Centigrade scale.

The scale approximates to the absolute scale defined by Lord Kelvin, on which the temperature of the freezing point is 273·1 to the nearest tenth of a degree.† Accordingly, to convert temperatures published in this volume to the Kelvin scale, a correction + 0·1 is to be added to each reading.

As an alternative to the application of this correction modified values may be used for the constants which enter certain formulæ. For example :—At temperature t on the scale adopted in the Year Book, the radiation according to Stefan's Law‡ is

$$5{\cdot}709\times10^{-5}\,(t+0{\cdot}1)^4 \text{erg/(cm.}^2\text{ sec.)}\ ;\ \text{or}\ 5{\cdot}717\times10^{-5}t^4 \text{erg/(cm.}^2\text{sec.)}$$

* This value depends on a coefficient of expansion of dry air of 1/273 and on the density of dry air at pressure 1013·23 mb. and temperature 273°A, viz., 1293·052 g/m^3.

† A. L. Day and R. B. Sosman, *Dictionary of Applied Physics*. Macmillan, London, 1922. Vol. I, p. 840.

‡ The constant 5·709 is the value which has been adopted by the International Research Council for publication in the "*International Critical Tables.*"

In using the modified formulæ we are virtually adopting a scale of temperature with the degrees greater than those of the Centigrade scale, in the ratio of 273·1 to 273. This is the practice of the *Computer's Handbook* of the Meteorological Office.

The tables give the values of temperature at exact hours obtained from the photographic thermograms; also daily, monthly and annual means of hourly values, together with the monthly and annual means of diurnal inequalities. There is also a table showing the daily extremes of temperature.

Humidity.—When the temperature of the wet bulb is above 273a, values of relative humidity at exact hours are deduced from the corresponding values of dry and wet bulb temperatures obtained from tabulations of the photographic thermographs, complete saturation being taken as 100. Until the end of the year 1925 the reduction was effected from tables based on Glaisher's hygrometric factors* but from 1st January, 1926, tables have been employed which proceed from Regnault's formula

$$x = f - Ap\,(t - t'),$$

where x = vapour pressure under the conditions of observation.
f = saturation vapour pressure at the temperature (t') of the wet bulb.
p = pressure of the air.
t = temperature of the dry bulb in absolute (Centigrade) degrees.
t' = temperature of the wet bulb in the same units.
A = a "constant."

The tables used in this volume for determining the hourly values of relative humidity when the wet bulb is above the freezing point are *Jelineks Psychrometer-Tafeln* (6th edition, Leipzig, 1911). They give values which are in almost exact agreement with those given by *Hygrometric Tables* published by the Meteorological Office in 1924 (M.O. 265) for general use at second and third order stations. The latter tables are not suited to the purposes of this Year Book, because in them temperature is expressed in Fahrenheit degrees, whereas the absolute centigrade scale of temperature is used at the observatories.

No allowance for variation of pressure p is made and the standard value used in Jelinek's tables, *i.e.*, 755 mm. of mercury (1006·57 mb.) is adhered to. Similarly no allowance is made in the adopted value of the constant "A" for the speed of the air flowing past the wet bulb, though it is well known that "A" is not independent of the ventilation. "A" is regarded as fixed and equal to ·0008. In view of the well-marked diurnal variation of wind-speed, the diurnal variation of humidity, derived in this manner, is subject to slight modification.

When the wet bulb reading does not exceed 273a, the above method of reduction is not followed, but values of relative humidity are derived from the record of the hair hygrograph. To these values are applied appropriate corrections based on a comparison between the readings of the record of that instrument and the corresponding values of humidity computed from dry and wet bulb readings during neighbouring periods when the wet bulb readings exceeded 273a.

The mean hourly values of vapour pressure are computed by slide rule from a table‡ of saturation vapour pressure over water, and the corresponding mean hourly values of relative humidity and air temperature.

---

* Glaisher's Hygrometical Tables, 7th edition, London, 1885.

‡ The saturation vapour pressures used are those employed in the preparation of *Hygrometric Tables*. They are equivalent to those published by Scheel and Heuse in *Annalen der Physik*, 1910.

The normal hourly values of relative humidity for the period 1886–1915, published for certain Observatories in "Hourly Values from Autographic Records, 1917," were derived from tables based on Glaisher's factors. The application of the new tables to the normal hourly values of dry and wet-bulb temperature gives results for normal relative humidity which are only slightly different from those which have been published. At Kew Observatory in winter the difference is negligible; in July it does not exceed 1 per cent. at any hour, in October it does not exceed 2 per cent. at any hour. The effect is greatest in April when the published normal values of average relative humidity are reduced by 3 per cent. at noon and at 16h. and by smaller amounts at other hours.

Of greater importance is the effect on the values of absolute minimum humidity. Under the old system, values of relative humidity less than 30 per cent. seldom occurred; under the new system, values less than 20 per cent. may occur not infrequently.

Tables are printed giving the values of relative humidity at exact hours together with daily, monthly and annual means of hourly values. Monthly and annual means of vapour pressure computed from the corresponding mean values of temperature and relative humidity, together with monthly and annual means of diurnal inequalities of relative humidity, are also given.

Rainfall.—Tables are given showing for the 60 minute intervals between exact hours* the amount of precipitation, expressed in millimetres, derived from the record of the Beckley gauge (see p. 11). Totals of amount are given for each day, and for each month; the latter totals referring both to the complete days of the month, and to each of the hours of the day. When zero rainfall is assigned to a particular hour, the entry appears as " ... ". Corresponding totals of durations of rainfall are also given, the duration being regarded as the number of hours during which rain falls at a rate of not less than 0·1 millimetre per hour. If slight precipitation, due to rain, snow, fog or dew, extends over some hours, and if the amounts collected in some or all of the hours are less than ·1 mm., the fact is indicated by a succession of entries, each of which is elclosed within brackets, covering the period over which precipitation is known or benieved to have occurred. In such cases entries of (·1) are allocated evenly among the hours concerned in such a way that their sum is equal to the aggregate fall during the period, and the remaining entries are (...), (*), (≡) or (≏) according as the precipitation took the form of rain, snow, fog or dew. Slight precipitation which takes other forms such as hail, sleet, hoar frost, glazed frost and rime is dealt with similarly. When it is impossible to determine the hourly amounts of precipitation, *e.g.*, during snowfall or on occasions when the record has failed, the normal procedure is to consider each case on its merits, and to assign hourly values derived from estimates made by the observers as soon as possible after the event. Such values are also enclosed in brackets.

Annual totals of hourly amounts and duration and notes on special features of the rainfall of the year are also given.

Sunshine.—Tables are given showing for each of the 60-minutes intervals between exact hours† according to *local apparent time*, from sunrise to sunset, the duration of bright sunshine recorded by the Campbell-Stokes instrument. The sums and means of hourly amounts are also given For each day is shown the total duration of bright sunshine, and also the percentage this represents of the "possible" duration for the day. The "possible" for each day is computed as the period of time beginning and

* For the years 1904 to 1920 it was the practice to tabulate rainfall for the period of 60 minutes centred at the exact hours; the reversion to the method in use before 1904 occurred on 1st January, 1921.

† Previous to 1st January, 1921, sunshine was tabulated for the period of 60 minutes centred at exact hours.

ending at the instants when the centre of the sun is apparently on the horizon, due allowance being made for atmospheric refraction. Even on a clear day the sun, when at an altitude less than $2\frac{1}{2}°$ to $3°$ above the horizon, fails to make a scorch on the card of the Campbell-Stokes recorder.

A distinction is made in the tables between (*a*) sunshine not possible, and (*b*) sunshine possible but none recorded. If, in any hour, sunshine is not possible, the symbol "—" is used; if more than 3 minutes of "possible" sunshine falls in the 60-minute interval between exact hours according to local apparent time, and if no sunshine was recorded the symbol " ... " is printed.

The values for the months and for the year of percentage of possible duration of sunshine are obtained by comparing the total recorded sunshine for the period with the total "possible" sunshine for the period.

Wind.—Tables are printed giving the hourly values of wind speed and direction, together with the mean speed for each day, each hour, and for the month and year. Values of speed are expressed in metres per second (1 metre per second=2·2369 miles per hour): those of direction are given in degrees from true north. The values of direction* and speed are averages for periods of sixty minutes, centred at the exact hours of Greenwich Mean Time. They are obtained by estimation from the records with the aid of a glass scale, the transparent part of which has a width corresponding with one hour on the time scale of the record.

For speeds not exceeding 1·5 m/s the wind directions are regarded as indeterminate and are omitted.

The daily values of the speed and time of occurrence of the maximum gust and the monthly distribution of wind are shown in other tables.

Minimum Night Temperature on the Grass.—Values are given for each day of the year together with monthly and annual mean values. The interval to which the reading refers is from 18h the previous day to 7h on the day to which it is entered.

Diary of Cloud, Visibility and Weather.—In these tables are given particulars of the cloud forms observed daily at 7h, 13h, and 18h, the total cloud amount observed at 7h, 9h, 13h, 15h, 18h, and 21h, the range of visibility at each of these six hours and the kind of precipitation which may be falling at those hours. There is also a column devoted to remarks on the weather of the day.

Cloud Form.—The observations of cloud form are made in accordance with the International classification, and the following abbreviations are used in the tables:—

Cirrus	Ci.
Cirro-Stratus	Ci-St.
Cirro-Cumulus	Ci-Cu.
Alto-Cumulus	A-Cu.
Alto-Stratus	A-St.
Strato-Cumulus	St-Cu.
Nimbus	Nb.
Cumulus	Cu.
Cumulo-Nimbus	Cu-Nb.
Stratus	St.
Stratus-cumuliformis	St-Cuf.
Fracto-(prefix, as in fracto-stratus)	Fr-.
-lenticularis (affix, as in stratus-lenticularis)	-lent.
Mammato-cumulus	M-Cu.

* Formerly it was the practice to take the direction at the exact hour. The present rule was adopted as from 1st May, 1915 (see also Introduction to *Hourly Values from Autographic Records*, 1913, p. xv.).

All the cloud forms noted by the observer at the time of observation are printed where space permits. When the number of forms is too great to allow of this, the predominating forms selected at the time of observation to give the best representation of the cloud canopy are printed. If high or medium cloud can be seen, one of the selected types is normally a high or medium cloud.

Cloud Amount.—The figure given for the amount of cloud denotes the proportion of the sky covered by cloud, the numerical scale running from 0, cloudless, to 10, completely overcast. The figure denotes the total cloudiness irrespective of form. In the case of fog through which it is impossible to discern the sun or stars the cloud amount is entered as 10, but if cloud can be seen through the fog, the form and amount of that cloud are entered in the usual way. If the sun or stars are visible through fog and if there is no evidence of cloud above the fog the amount is entered as 0.

Visibility.—Observations of the range of horizontal visibility made every day at 7h, 9h, 13h, 15h, 18h, and 21h, are printed in the diaries of cloud and weather.

As described in detail in the *Meteorological Observer's Handbook* (Ed. 1926), a series of selected objects, A, B, C..., as nearly as possible at the standard distances given in the table which follows, are used for this observation. The objects are selected so as to be readily seen and identified from specified observing points in daylight.

SCHEME FOR OBSERVATIONS OF RANGE OF VISIBILITY AND OF FOG, MIST AND HAZE.

Indication Letter of Object.	Standard Distance of Object.	Verbal Description.	Beaufort Letters.	
			Detailed Scale.	Contracted Scale.
	Metres.			
(X)	—	Dense fog	8 f	F
A	25		7 f	
B	50	Thick fog	6 f	
C	100		5 f	
D	200	Fog	4 f	f
E	500	Moderate fog	3 f	
F	1,000	Mist, haze or very poor visibility	m or z	m or z.
G	2,000	Poor visibility	m_o or z_o	m_o or z_o
H	4,000	Moderate visibility		
I	7,000			
J	10,000	Good visibility		
K	20,000	Very good visibility		
L	30,000			
M	50,000	Excellent visibility		

Note.—The grouping of the letters by the horizontal lines indicates the limits of the several figures of the International Telegraph Code for visibility, from 0 to 9, which grouping is also adopted in the tables of frequencies published in the *Monthly Weather Report.*

when the air is clear. A variation up to 10 per cent. from the standard distances is considered admissible. Particulars of the objects in use at each observatory, together with a statement of their actual distances and bearings from the point of observation and notes on local peculiarities which affect the observations, will be found in the Introductions to the sections for the individual observatories.

The method of observing consists in determining which is the most distant of the selected objects that can be identified and entering the corresponding letter. In cases of uncertainty when the observer, though recognising the presence of an object, would be unable to identify its nature from the observations he is able to make *at the time*, the letter corresponding with the next nearer object is entered. If object A, the nearest of the selected objects cannot be identified, an entry X is made. At night the letters are used to denote as nearly as possible corresponding degrees of atmospheric obscurity.

Small letters are used to indicate interpolations or extrapolations made in cases where it has not been possible to find suitable objects within 10 per cent. of the standard distances. In such cases the observer may use objects at other than the standard distances to guide his judgment. Particulars of such auxiliary objects will be found in the sectional introductions.

At Cahirciveen, visibility is recorded in both landward and seaward directions. The observations of visibility landwards are printed in the main tables. Particulars of occasions when visibility seawards differed from visibility landwards are set out in the Introduction to the Cahirciveen Section.

Fog, Mist and Haze.—The table of standard distances of visibility objects also summarizes the descriptions used in connection with the phenomena of fog, mist and haze, and relates them to the scale of visibility. It also contains the Beaufort letters used for these phenomena in the Remarks column of the diary. In this Year Book as in other publications of the Meteorological Office, statistics of fog, mist and haze are based solely on visibility observations. The term *fog* is restricted to occasions when the visibility is less than 1 kilometre (*i.e.*, object F not visible); the terms *mist* and *haze* to occasions when the visibility is greater than 1 kilometre, but less than 2 kilometres (*i.e.*, object "F" visible, but "G" not visible). The distinction between mist (m) and haze (z) is determined by the depression of the wet bulb. When the visibility is between the limits specified for mist or haze, haze is recorded when the depression of the wet bulb is more than 1°F; if the depression of the wet bulb does not exceed this limit, the term *mist* is used.

In volumes previous to 1926, occasions of haze, mist and fog were indicated by the International symbols for these phenomena, viz., ∞, ≡ ° and ≡ respectively, but the relation of these terms to the visibility scale was less rigorous. In order to indicate that a change in procedure has occurred in this matter, the three International symbols for haze, mist and fog are no longer used.

Precipitation.—Whenever precipitation is falling at one of the six hours of observation there is printed in the Diary of Cloud and Weather under the heading "Precipitation" the International weather symbol which indicates the kind of precipitation, in accordance with the list below.

Remarks.—For the purposes of the column headed "Remarks on the Weather of the Day," it is usual to consider the day as divided into three portions, viz., morning, afternoon and night, denoted by *a*, *p*, *n*, respectively, but it should be noted that no arrangements are made for regular eye observation of weather changes in the period 21h 30m to 6h 30m.

The entries in the remarks column consist very largely of international weather symbols and the letters of the Beaufort scale. These symbols and letters are as follows:—

Beaufort Notation and International Weather Symbols.

b		blue sky, whether with clear or hazy atmosphere.
c		cloudy, *i.e.*, detached opening clouds.
o		overcast, *i.e.*, the whole sky covered with one impervious cloud.
g		gloomy.
u		ugly, threatening.
v	()	visibility, unusually clear of atmosphere.
z		haze.*
m		mist, light fog.*
f		fog.*
fe		wet fog, *i.e.*, fog which deposits water copiously on exposed surfaces.
w	⊔	dew.
x	⊔	hoar frost.
	V	rime.
	~	glazed frost.
e		water deposited copiously on exposed surfaces, without rain falling.
y		dry air. (Relative humidity less than 60 per cent.)
p		passing showers.
d		drizzling rain.
r	●	rain.
	←	ice crystals in the air.
s	✳	snow.
rs	✶	sleet.
	⊰	drift snow.
	⊠	snow lying. (More than half the surrounding country covered with snow.)
h	▲	hail.
	△	soft hail.
t	⊤	thunder.
l	↘	lightning.
tlr	↯	thunderstorm.
	≋	gale.
q		squalls.
	⊙	solar corona.
	⊕	solar halo.
	∪	lunar corona.
	⊍	lunar halo.
	⌒	rainbow.
	⩔	aurora.
	⟍	zodiacal light.
	⋈	mirage.

The letter *i* preceding a letter or symbol which denotes some form of precipitation indicates that the precipitation is of an "intermittent" or "occasional" character.

The letter *j* preceding a letter or symbol which denotes some form of precipitation indicates that the precipitation is within sight, though not actually falling at the station.

The figure 0 written after and above a symbol indicates slight, whilst the figure 2 indicates strong or heavy; thus $\bullet^0$ slight rain, $\bullet^2$ heavy rain. The figures 0 and 2 written after and below the letters of the Beaufort notation are also used with a similar significance, thus d_0 stands for slight drizzle.

The letters b, c, o, g and u, are used to describe the general appearance of the sky. The use of the letters g and u is sufficiently clear from the definitions given above. o is used whenever the sky is completely overcast with a uniform layer of thick or heavy cloud; c is used to denote that there is some cloud present, but o is not appropriate; b denotes that there is some blue sky.†

In order to meet difficulties which occur when there are only small quantities of cloud or blue sky present, c is not used unless the sky is more than a quarter covered, and b unless there is more than a quarter of the sky free from cloud. If there is more than a quarter of the sky covered with cloud and more than a quarter of the sky free from cloud b and c are both recorded.

The gale symbol ≋ is normally used in this publication to indicate that the wind as recorded by the anemograph averaged at least 17·2 *m/s* for one or more "centred" hours. At Richmond (Kew Observatory) the symbol has been used with the word gust in brackets to indicate the occurrence of gusts reaching 17·2 *m/s*.

---

* To indicate varying intensities of haze, mist and fog the notation shown in the last two columns of the table on p. 18 is used.

† The present usage with regard to b, c and o dates from 1st Jan., 1926.

INTRODUCTION.

GENERAL REMARKS.

In 1919 the establishment of an observatory in the Shetlands was included in the programme of the Meteorological Office. A wireless station, built in 1913 by the Admiralty and transferred after the war to the Post Office, but used by that Department only in case of emergency, offered suitable accommodation in the way of offices and living quarters. It proved possible to make an arrangement under which the Air Ministry has the use of the station as an observatory.

The Observatory was opened on the 7th June, 1921, when the first instalment of the instrumental equipment arrived. Later on in the same year the construction of a magnetograph house and of huts for absolute magnetic and auroral observations was commenced. The magnetograph house is a heavy concrete structure with walls 2 feet 6 inches (76 cm.) thick, of internal dimensions 16 feet by 10 feet (4·9 m. ×3 m.), and after construction several months had to elapse before the thick concrete walls and roof could be thoroughly dried and the recording instruments placed in position. These instruments, which are described below, consist of magnetographs recording magnetic declination and horizontal and vertical force. During 1928 subsidiary magnetographs recording declination and horizontal force were installed in one of the adjacent non-magnetic huts; the records obtained therefrom are used to cover lacunæ in the standard traces or for special investigations. In addition, in order to obtain a record of the more minute changes in the vertical component of terrestrial magnetic force, a line of twin cable was laid in an approximately horizontal plane round Loch Trebister, the terminals of the cable being connected to a suitable galvanometer on which could be measured the current induced in the cable by changes in the vertical component of terrestrial magnetic force. The arrangement is similar to one in use at Eskdalemuir Observatory, but no records from either have yet been included in official publications.

Other instruments installed at the Observatory included barometers, barograph, hygrograph, psychrometers, nephoscope, raingauges (ordinary and self-recording), sunshine recorder and Dines tube anemograph and, later, an electrograph; and in 1928 a Krogness auroral camera. But meteorological observations have been restricted, and the time of the somewhat limited staff available has been devoted chiefly to magnetic work, to some work in atmospheric electricity and latterly to auroral photography.

The site and the work in Atmospheric Electricity and Terrestrial Magnetism will now be described.

SITE.

The Observatory is situated on a ridge of high ground about a mile and a half (2·4 km.) to the south-west of Lerwick and adjoins the main road between Lerwick and Scalloway. The site slopes upward from west-north-west to east-south-east, the average height above M.S.L. being about 280 feet (85 metres). The ground to the east and south-east rises slightly for about $\frac{1}{4}$ mile (·4 km.) then slopes sharply down to the sea. In other directions there is a downward slope for about $\frac{1}{4}$ mile extending to the Loch of Trebister on the south-west, Sandy Loch to north-west, and to the Burn of Sound to north-north-west ; beyond these and distant about $\frac{3}{4}$ mile (1·2 km.) from the Observatory are small hills—Munger Hill to the south is about 320 feet (97 metres) above M.S.L., Shurton Hill to west-north-west rises to 576 feet (176 metres), and Stony Hill to the north to about 400 feet (122 metres). In clear weather it is possible to see the Outer Skerries, $25\frac{1}{2}$ miles (41 km.) north-east by north, and Sumburgh Head, 20 miles (32 km.) south by west ; the horizon in other directions is limited to a few miles.

The average depth of soil in the vicinity is about a foot, and outcrops of sandstone occur in many places. The surrounding country is barren and desolate, the only vegetation being coarse grass, stunted heather, and moss, with occasional patches of bare black peat. The Observatory ground is of a very uneven nature, and, owing to lack of proper drainage, is frequently water-logged ; in winter it may be almost submerged for considerable periods. Views of the station are shown and the arrangement of buildings and situation of instruments are set out on a site plan in the 1928 Year Book.

ATMOSPHERIC ELECTRICITY.

Notes on the Instruments.—The records of potential gradient are obtained from a Benndorf electrograph (No. 108, by L. Castagna, Wien) which since 1926 has been installed in the north-west corner of the Office Block. The site is divergent from the ideal for two reasons :—

(1) There is distortion of the equipotential surfaces by adjacent houses, wireless plant, etc.,

(2) It is a comparatively large distance (236 metres) away from the ground where absolute determinations are made.

Consideration of the variations of mean monthly values of the reduction factor shows that these disadvantages are less serious than might be anticipated.

The collector rod passes through a window in the north wall, and is situated 190 cm. from the corner of the building. The collector, which is 476 cm. above the ground and projects 123 cm. from the window, consists of a copper spiral about 5 cm. long, painted over, by means of a special adhesive varnish, with a salt of radium. The collector is soldered into the smaller end of a tapered German silver tube, 76 cm. long, and of triangular cross section, which, in turn, is attached to a " Duralumin " tube, 89 cm. long and 1·3 cm. in diameter. The latter tube passes through a hole, 3·8 cm. diameter, in one end of a wooden box (dimensions 38 × 25 × 10 cm.), where it is supported horizontally between the ends of two metal rods embedded in sulphur. A number of small 2-volt electric bulbs are kept burning inside the box in order to improve the insulation of the supports for the collector rod during wet weather, and a similar bulb is placed inside the case of the electrometer. The rod is connected to the base of the acid pot of the Benndorf electrometer by a fine wire. A detailed description of this instrument is to be found in *Phys. Zeit.* 7 (1906), p. 98, whilst the general principle is described in Mathias' *Traité d'Electricité Atmosphérique et Tellurique*, p. 54, and in Chauveau's *Electricité Atmosphérique*, pp. 61–64.

The record consists of a series of dots made once a minute on a long roll of paper as it is unwound from a drum by clockwork, exact hours being indicated by dots near the edge of the sheet. Timing is taken from electric clock No. 1,031, governed by the Observatory standard, Shelton No. 35. The needle of the electrometer is earthed at least twice daily, and a zero line is obtained by connecting up these earth marks; owing to the constancy of the perpendicular distance between the zero line and the line through the hour marks, further intermediate positions of the zero are easily obtained. The scale value has been about 21 volts per millimetre, which permits a range from +1700 to −1100 volts per metre in the open to be recorded.

Combined tests of the insulation of the system and scale value of the record are made daily, the procedure being to remove the collector and to charge the needle, which is connected to a Wulf electrometer. The rate of leak is obtained for a period of 4 minutes with a positive charge and for the same interval with a negative charge. Considering the climatic difficulties the behaviour of the instrument in the matter of insulation has been very satisfactory. The rate of leak has been in general small, the average during 1929 being such that the instrument would lose half its potential in 69 minutes. It has been found that the scale value remains reasonably steady and may, for all practical purposes, be taken as constant across the full width of the sheet. The factor by which the recorded potential must be multiplied for conversion into potential gradient in the open is obtained from absolute measurements above a levelled piece of ground near the old site of the electrograph (see site plan in the Observatories' Year Book, 1928). An insulated wire, stretched horizontally between two stout wooden posts 121 cm. in height and 9·48 m. apart, carries at its centre a burning fuse exactly 1 metre above the ground. Wulf electrometer, No. 5225 (Günther & Tegetmeyer, Braunschweig), is connected to one end of the wire and ten to twenty readings are obtained from the electrometer at minute intervals. The reduction factor is deduced from the mean of these values and the corresponding mean potential at the collector as recorded by the Benndorf electrograph. Smoothed monthly means of factors so obtained are employed in reduction of the records.

There was no change in any essential part of the apparatus or in the observational technique throughout the year 1929.

Monthly scale values and exposure factors, together with data relating to rate of leak, are shown in the following table:—

	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year.

*Changes of Scale Value occurred on 7th May, 9th and 24th August.

In its response to changes of potential gradient the Benndorf instrument is very sluggish, compared, for instance, with the Kelvin water dropper in use at Eskdalemuir Observatory. A series of tests in 1929 gave 45 seconds as the time to rise to half

value, the rise being assumed to follow an exponential law. Sometimes when there is no wind the rate of rise of potential is very much slower and apparently nearly linear. If the instrument rises through a potential V and has a capacity C a quantity of electricity CV has to be given to the air in the neighbourhood of the collector, and in the absence of wind and the presence of fog this may hang about in the form of a heavily charged cloud for a considerable time before being dispersed. It is difficult to accept the readings from a radio-active collector during such times. Fortunately these conditions are rare at Lerwick except in early summer, but on the other hand they are then very interesting.

If we assume the leaking and the charging to be exponential, i.e.,—

$$\text{If } \frac{dV}{dt} = -K_L V$$

$$\text{and } \frac{d(V_o - V)}{dt} = K_C (V_o - V)$$

where K_L measures the rate of leak,
and K_C ,, ,, charging,

then the potential finally acquired by the instrument is equal to the real potential multiplied by $K_C/(K_L + K_C)$.

In 1929 the mean monthly value of K_L/K_C varied from 1/60 to 1/130, so that the electrograph generally recorded a potential gradient not less than 98 per cent. of the true gradient. The corresponding values of the fraction for 1928 were such that the registered potential gradient varied between 95 per cent. and 98 per cent. of the true gradient. This change is reflected in the mean values of the exposure factor for the two years, these falling from 1·31 in 1928 to 1·26 in 1929. Though at most only partly responsible for the month-to-month changes of the factor it is not unlikely that the 1929 seasonal variation in the rate of leak of the electrograph contributed to the variation in exposure factor during that year. The vegetation in the vicinity of the site for the absolute observations changes very slightly throughout the year and the grass on the site itself is kept short. A larger contribution to the variations of the factor is probably made by the combination of effects due to peculiarities of the electrograph site and wind direction. In this connection the following table shows the mean values of the exposure factor for 1927 and 1928 summarized according to wind direction :—

	Calm.	N	NE	E	SE	S	SW	W	NW	1927–28
Mean Factor	1·35	1·33	1·37	1·27	1·24	1·37	1·36	1·35	1·29	1·33
No. of Observations	24	19	16	12	21	44	28	21	26	211

Relatively high values of the factor are associated with winds from north-east, south, south-west, and west, for which directions the electrograph collector has a good exposure. The exposure in other directions is obstructed by adjacent buildings, and the depression of the factor depends upon the proximity of these obstructions to the collector. The lower factors, resulting from the higher potential of the collector when shielded from the wind, also follow from R. A. Watson's conclusion that potential gradient is inversely dependent upon wind speed. (Geophysical Memoir No. 38). Wind direction, however, appears to have no appreciable bearing upon the annual variation of factor discussed in the preceding paragraph.

On 28th June, 4th July, and 12th September, 1928, measurements were made of potential gradient above fairly smooth ground near sea level. The determinations on the two earlier dates were taken at the Point of Trebister, 2¼ km. south-south-east of the Observatory, those on the third near the Sands of Sound, 1 km. to the east. In all, ten series of observations were obtained. The mean electrograph exposure factor computed therefrom works out at 1·36, a value in close agreement with the standard determinations.

IDENTIFICATION NUMBERS OF INSTRUMENTS USED IN 1929.

Benndorf electrograph (L. Castagna, Wien)	108
Wulf bifilar electrometer (Günther & Tegetmeyer, Braunschweig)	5225
Electrostatic voltmeter (Cambridge Instrument Company)	11889

Review of Results—Days when there was a complete trace have been classified as follows by means of an electric character figure :—

0, denotes a day during which, from midnight to midnight, no negative potential was recorded.

1, denotes a day with excursions to the negative not amounting in the aggregate to more than three hours.

2, denotes a day with negative potential amounting in the aggregate to more than three hours.

a, denotes that the range of potential gradient in the open did not exceed 1,000 volts in any of 25 hourly periods of the day.

b, denotes that this range was exceeded in at least one, but in fewer than six, of these periods.

c, denotes that this range was exceeded in six or more of the hourly periods.

The character figures so assigned are given in Table 4.

In the Observatories' Year Book for 1928, for the first time, this table contained also details of the duration of negative potential for each day for which an estimate could reasonably be made. If the record failed when no precipitation fell it was assumed that the potential gradient remained positive ; if, however, precipitation fell when part of the record was lacking no estimate was made except when the part of missing record was small enough and the conditions of precipitation sufficiently continuous to permit the interpolation of the gradient conditions from those obtaining before and after the lacuna.

Over the year 1929 there were 25·3 hours less negative potential gradient than in 1928, but only 2 days less on which negative gradients did occur. Against the mean daily duration of 1·63 hours for 1928, that for 1929 was 1·55 hours. In both years there is a close parallelism between the month-to-month variations of mean duration of negative potential and the monthly mean electric character figure, and again between either of these quantities and the monthly totals of rainfall.

Curves are read by use of a mean value glass scale graduated in millimetres, the tabulated values being 60 minute means centred at exact hours G.M.T. The ordinates are converted into volts per metre in the open by multiplying by the product of the appropriate scale value and reduction factor. Values are assigned for 3h, 9h, 15h, and 21h, on all days, and for each hour on "*a*" days.

An indication of the characteristics of indeterminate potentials may be obtained from the tabulations, in which :—

(1) z is marked against hours when there occurred large oscillations of small period which are not accurately reproduced in the record. The signs +, −, following the z indicate on which side of zero the mean value lay ; for values marked $\pm$ the sign of the mean value was uncertain.

(2) values prefixed by the symbols $>$, $<$, indicate that for one or more periods during the hour potential passed beyond the range recorded by the electrograph.

The hourly values for 3h, 9h, 15h, and 21h are given in Table I ; estimated values, enclosed within brackets, are given in cases where the record was in some manner defective, a dash is entered against hours for which no value can be given with any degree of assurance. Two sets of mean monthly values at the four selected hours are given below each month's data; the first set (*a*) represents the arithmetic mean of all the hours of positive potential gradient in the corresponding column, and the second set (*b*) represents the algebraic mean derived from all days for which values for all four selected hours are available. The means from the four values (*a*) and (*b*) for each month may be expected to approximate closely to the true monthly mean, the (*a*) values representing all days when negative gradients are excluded and the (*b*) values representing all days inclusive of those with negative gradients. The indeterminate values $z \pm$ can naturally not enter into either set of mean values.

In all months except July the general (*a*) mean from the four selected hours exceeds the (*b*) mean, the difference over the year as a whole amounting to 28 v/m. The monthly mean daily values derived from the 0*a* days are in seven months greater than the (*a*) means but over the year the 0*a* day mean is only 1 v/m greater than the (*a*) mean. The annual mean daily values derived in these three ways for the three years 1927–1929 during which the electrograph has been in the same position are :—

	0*a*	(*a*)	(*b*)
1927	213 v/m	179 v/m	160 v/m
1928	166 v/m	156 v/m	134 v/m
1929	162 v/m	161 v/m	133 v/m

It is a defect of the Benndorf recorder that even with such a high scale value as 22 v/mm the width of the sheet is frequently exceeded during oscillatory movements. In 1929 there were 53 days on which the electrometer needle went beyond the limits of registration on the positive side and 118 on the negative side ; the occasions being mainly when precipitation was falling on the collector. The greatest number of extreme positive excursions were associated with snow or sleet showers and were almost invariably only momentary.

The following table summarises the occasions of highest potential gradients of both signs persistent over periods of at least one hour, a specified hour defining the 60 minute interval centred at the exact hour G.M.T.

Occasions of highest potential gradients.

Positive.

Day.	*Hour.*	*Mean Value.*	*Conditions.*
March 9 . .	19h	774 v/m	Mist or fog
,, 9 . .	16h–20h	622 v/m	Mist or fog
,, 10 . .	17h	806 v/m	Mist or fog
,, 10 . .	16h–19h	691 v/m	Mist or fog
April 20 . .	6h	>1079 v/m	Snow, very oscillatory
July 18 . .	14h–16h	651 v/m	Fog

Aug. 3	22h–23h	830 v/m	Mist after rain
Sept. 11	19h	799 v/m	Mist or fog
,, 24	18h–22h	560 v/m	Fog
,, 26	15h–20h	570 v/m	Fog

Negative.

Jan. 21	5h	<-1140 v/m	Rain
Feb. 6	20h	<-1119 v/m	Rain
March 5	9h	-1028 v/m	Rain
Sept. 18	2h	<-1080 v/m	Rain
,, 19	12h	<-1080 v/m	Rain
Oct. 4	7h–10h	<-1096 v/m	Rain
Dec. 28	8h	<-1127 v/m	Rain

Occasions when the potential gradient was negative for prolonged periods with perhaps only a few temporary changes to positive were noted as follow :—

January, 20d 22h 7m to 21d 5h 54m. Mean potential gradient <-536 v/m during continuous rain.

March, 2d 0h 15m to 2d 7h 58m. Continuously negative except for three short excursions to positive side, mean gradient -89 v/m during continuous rain.

April, 4d 0h 0m to 4d 10h 45m. Became just positive for three isolated minutes, mean -191 v/m during continuous rain.

June, 22d 22h 15m to 23d 2h 47m. Continuously negative, mean -519 v/m during rain.

October, 4d 7h 4m to 4d 10h 0m. Continuously <-1100 v/m during rain.

October, 6d 4h 0m to 6d 9h 20m. Negative except for two limited excursions to positive, mean <-421 v/m during rain.

November, 11d 12h 15m to 11d 17h 48m. The total duration of negative potential for November 11 was 10·7 hours, being continuously negative, except for one minute, with a mean potential gradient of <-515 v/m from 12h 15m to 17h 48m and with a further period of continuous negative gradient of average <-1060 v/m from 4h 33m to 6h 12m ; the occasion was one of continuous rain.

December 21d. The total duration of negative potential was 16·1 hours, associated with continuous rain. From 1h to 19h it was wholly negative except for short excursions of limited duration to positive side ; the mean potential gradient over the period for which complete trace is. available was <-323 v/m.

December, 29d 1h 15m to 29d 8h 50m. Except for three short intervals of low positive potential gradient, continuously negative with a mean of -76 v/m associated with continuous rain.

October, 2d 15h to 24h was a period of highly variable gradient during intermittent rain showers. Ten times during these nine hours the potential gradient exceeded $+810$ v/m and eleven times was less than -810 v/m. It exceeded $+1600$ v/m from 15h 0m to 15h 15m, at 19h 0m, at 19h 30m, and at 23h 25m ; from 17h 10m to 17h 20m, at 17h 50m, and at 20h 45m the gradient was negative and <-1085 v/m

There were 45 days on which there occurred apparent changes of potential gradient from the limit of the sheet on the positive side to the limit on the negative side, at least once within an interval of 60 minutes. If these changes were real and not due to charges given to the collector boom by precipitation, they connote a range of at least 2600 v/m within an hour. In some of the hours the extreme reversal occurred at least twice within the period.

The diurnal inequalities for 0*a* days for the months, seasons, and year, are given in Table 2, together with mean values of the potential gradient and particulars of the non-cyclic change and the number of days used ; the inequalities and other entries for the seasons and year are the means of the corresponding entries for the appropriate months. Similar data for the 1*a* and 2*a* days together are given in Table 3.

As compared with the annual mean diurnal variations for 0*a* days for 1927 and 1928, the variation for 1929 has almost lost the secondary forenoon oscillation, retaining only a pronounced single oscillation with minimum about 2h and maximum at 20h. In the separate mean variations for the equinoctial and summer months, however, the secondary oscillation is present, being most marked and with an earlier maximum at 6h in the summer months. The principal evening maximum at 20h persistent throughout these two seasons is advanced to early afternoon in winter. Inequalities for all the remaining days of 1929 which contained no hour of range exceeding 1000 v/m, but in which negative potential gradients occurred, i.e. 1*a*+2*a* days, are naturally more irregular and show less tendency to a secondary variation in the early forenoon. The evening maximum in the period 18h to 20h is the principal feature of the variation ; the mean variation for the equinoctial months has its minimum at 10h instead of 2h or 4h as for the other two seasons. This feature of a retarded minimum in the equinoctial months is to a less extent apparent in the 0*a* days.

In both classes of days, 0*a* and $\overline{1a + 2a}$, the seasonal mean daily values derived from the inequalities increase from winter to summer ; this is also true of the two sets of daily means (*a*) and (*b*) of Table I deduced from the values at the four hours each day. But whereas the equinoctial mean values for the former classes are intermediate between those of the other solstitial seasons, those for the (*a*) and (*b*) means from the four hours per day are less than the mean for winter, though only by 1 v/m in the case of the (*b*) means for all complete days.

TERRESTRIAL MAGNETISM.

Notes on the Instruments.

The standard records of declination and horizontal and vertical force are obtained from the Munro magnetographs which were in use at Falmouth until 1912. The instruments had been stored for several years, but were afterwards reconditioned ; the declination and horizontal force instruments were tested at Kew before being installed at Lerwick in November, 1922.

The declination magnet has a unifilar suspension, and the torsion correction is negligible. The scale value is constant for all positions of the light dot on the sheet ; throughout the year it was 1 mm. of ordinate to 1·93 minutes of arc. In the horizontal force instrument the magnet is maintained in a position approximately perpendicular to the magnetic meridian by torsion of the bifilar suspension. The vertical force balance consists of a single heavy magnet similar to those used for recording declination and horizontal force, and may be compensated for variations of temperature. Copper damping plates are fitted to each instrument and the recording mechanism is similar to that used at Eskdalemuir. The arrangement of the instruments in the magnetograph house is shown in the Observatories' Year Book, 1928.

The vertical force constituent of the Munro magnetograph set was removed to the auxiliary recording house at the latter end of November and continued as the standard instrument until 31st December, 1929. A new instrument of the Watson quartz fibre type and supplied by the Cambridge Instrument Company was installed in the standard recording house at the end of November and became the standard vertical force instrument from 1st January, 1930.

With the Munro V variometer freed a complete auxiliary magnetograph can be maintained, the other constituents being a Krogness H magnetograph and a locally adapted declination instrument. The hut intended for eye-reading variometers during auroral displays has been lined with thermally low conducting Celotex and fitted with a light-tight porch so as to form a more satisfactory subsidiary recording house. The auxiliary records arranged to function at a low sensitivity have already proved their usefulness in supplying record during highly disturbed hours.

The chief instrumental defects encountered during the year were :—

(*a*) A slight irregular drift in the case of the horizontal force instrument ; corrosion of the tungsten wire used for the suspension of the magnet caused a breakage to occur on 1st September.

(*b*) Unsteadiness of the vertical force system. The instrument was adjusted on the following dates :—8th February, 20th March, 24th April, 6th and 29th May, 20th June, 3rd July, 28th September and 25th November, on which last date it was dismantled and removed to the subsidiary magnetograph house.

(*c*) Irregular changes in declination base line values. These seem to be of two kinds, some appearing as abrupt discontinuities explainable by slight internal friction in the 16-strand silk suspension, others being slow changes like positive and negative bays with a period up to three weeks within which the base line values slowly diverge from and subsequently re-attain their theoretically expected straight run. These latter changes are frequently synchronous with corresponding warm and cold spells (after allowance is made for the temperature lag through the magnetograph house walls) and are probably bound up with a differential distortion of the magnetograph, the case upholding the suspension tube being of wood whereas the base line mirror rests on the slate slab forming the top of the pillar.

Monthly scale values have been assigned to the records by taking overlapping means, except when discontinuities occurred and special measures were required. The determinations are made by Broun's method, the deflecting magnet being placed in the " broadside on " position and at a distance of 55·9 cm. from the recording magnets. A larger deflection distance would render the error due to inequality of the distribution coefficients for the H, D and V magnets less appreciable, but cannot be used owing to the restricted size of the magnetograph house. The scale value of H was maintained at approximately 6 γ/mm. ; for the V magnetograph the scale value increased from 12γ/mm. in January to 30 γ/mm. in September and during the last three months of the year it was kept at about 19 γ/mm.

The records of declination, horizontal force and vertical force have been tabulated hour by hour. The values are read off by means of graduated glass scales, a value being the mean reading for 60 minutes centring at the hour.

Base values for the records are obtained from the results of absolute observations, the determinations of declination and horizontal force being taken at least twice weekly, those of dip five or six times in each week. Horizontal force and declination are determined with Unifilar No. L 3951 (Cambridge Instrument Co.) using magnets 3951A and 3951C. The magnetometer is used on the centre pillar (No. 2) of the absolute hut, the azimuth of the fixed mark being taken as 8° 43′ 2″ east of south. Inclination is measured with Dover Circle No. 238 placed on the East pillar (No. 3), using $3\frac{1}{2}$ inch needles. In the deflection experiment three distances 25, 30 and 35 cm. are used for obtaining the distribution coefficients, the horizontal force being computed from the deflection at 25 cm. only.

Mean annual values of the P and Q correction have been derived from observations during the period March 1923 to the end of 1929. An accident caused some change to the magnet in March 1923, and values for earlier months have been discarded.

The values during these years are as follows :—

Year.	P.	Q.	$\log_{10}(1+P/25^2+Q/25^4)$.
1923 (March–December) ...	−2·398	−14·36	$\bar{1}$·99831
1924	−1·236	−464·6	$\bar{1}$·99862
1925	−1·165	−875·9	$\bar{1}$·99821
1926	+1·225	−1711·2	$\bar{1}$·99895
1927	+2·229	−2183·8	$\bar{1}$·99912
1928	+0·223	−1395·6	$\bar{1}$·99860
1929	−0·539	−968·5	$\bar{1}$·99855

The mean value of $\log_{10}(1 + P/25^2 + Q/25^4)$ employed in the reduction of all observations for 1929 was the mean of the values derived up to the end of 1928, namely, $\bar{1}$·99864. If the 1929 value is added, the mean for the total available period becomes $\bar{1}$·99862. The adoption of this latter value would raise all the hourly values, monthly means, etc., as given in the tables by 0·3γ in the case of H and 1γ in the case of V.

As stated in the general remarks the walls of the magnetograph chamber are of concrete, 2 feet 6 inches in thickness. The diurnal variation of temperature within the chamber is, for most days of the year, negligibly small and no corrections for this diurnal variation have been applied to the diurnal inequalities or other data published in this volume. From the magnetograph house temperatures for each day given in the Tables, however, it will be noted that the day to day change of temperature is sometimes considerable. The average change day-to-day in degrees absolute over each of the twelve months of 1929 and for the year as a whole was as follows :—

Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year
0·40	0·45	0·33	0·37	0·31	0·33	0·37	0·23	0·31	0·30	0·45	0·35	0·35

There were 15 occasions on which the change reached or exceeded 1°A. These rapid fluctuations of temperature obviously add considerably to the problem of satisfactorily determining base line values in the cases of the horizontal and vertical force magnetographs. The temperature coefficient of the former is known with fair accuracy, being taken to be 6·1γ per 1°A. ; consideration of the trend of base values indicates that the error introduced by omitting to apply a correction for temperature of the magnetograph is usually less than the error of observation and that it would be desirable to have absolute observations made more frequently than twice weekly. For another reason, namely that magnetic disturbance at Lerwick is so much more frequent and so much more considerable than at more southerly observatories, it would similarly be desirable to have very frequent absolute observations, with a view to the retention only of those made at times when the autographic records indicate a reasonably constant magnetic field. With the existing staff and instruments it has not, however, been possible to contemplate any increase in the observations of horizontal force.

In the case of the vertical force, the magnetograph appears to be subject to a thermal hysteresis sufficiently large to render ineffectual any method so far tried of making allowance for the fluctuations of temperature in the chamber. It has not therefore been possible to bring into close accord with one another the base line values deduced from individual absolute observations. So long as these conditions exist the hourly values of vertical force must be regarded as of a somewhat lower order of accuracy than might be desirable. The diurnal inequalities are not of course subject to any appreciable uncertainty on this account ; the uncertainty only arises where for instance the mean value for a given day or series of days comes to be compared with that for another day or series of days.

Again, owing to the smallness of the chamber, the presence of an observer for a short time, as, for instance, during a scale test, causes an appreciable rise in temperature and this seems to be reflected in the record of vertical force in the form of a fairly rapid rise and afterwards a slow recovery to normal. The effect on the record is so characteristic that an approximation to the undisturbed curve can in general be drawn in with considerable confidence, and this has been done where the duration of the visit of an observer was sufficient to make the magnitude of the effect noticeable.

AURORA.

From about September to April a watch for aurora is maintained, normally until about 23h G.M.T. each evening, and observations—as a rule at intervals of 15 to 20 minutes—are made of the northern horizon and of general meteorological conditions. The records form what is called the auroral log, a brief summary of which is given in Table 67. When any auroral display is observed, a second observer is called and detailed observations are maintained until the display subsides. These detailed observations have continued to be mainly non-instrumental and have consisted in noting and making descriptions of the phenomena seen during the display, but from October auroral photography was attempted with the Krogness camera whenever the manifestation was sufficiently bright. The descriptive notes are entered in a second log reserved for records of actual auroral displays. Extracts from this latter log may be obtained by anyone requiring the detailed information.

A general auroral table for Scotland (Table 68) is also included. This table has been compiled from the records of all stations at which climatological observation or weather logs are maintained. The observers at these stations, whilst noting occasions of aurora which they may happen to observe, do not in general maintain a special watch.

Notes on the Tables.

The hourly values of H, D and V, obtained as described above, appear in three of the four monthly tables. The variations in D, being expressed in minutes, may be readily converted to units of force (γ) of the component perpendicular to the magnetic meridian by multiplying by a factor which for 1929 is approximately 4·25. A rough comparison of the H, D and V registrations with component registrations (geographical N and W, and V) as for instance at Eskdalemuir, can then be easily made. The mean value for the day is computed according to the expression :—

$$x = \{\tfrac{1}{2}\,(x_0 + x_{24}) + x_1 + x_2 + \ldots\ldots\ldots\ldots + x_{23}\}/24.$$

The letters " Q " and " D," prefixed to dates, denote the five quiet and the five disturbed days as selected at De Bilt.

In the fourth table for each month are given :—

(*a*) The values and times of the daily maximum and minimum and the values of the absolute daily range for each of the elements H, D and V.

(*b*) The value of ΣR^2 for each day. ΣR^2 is written for $R^2_H + R^2_D + R^2_V$ where R_H, R_D and R_V denote the absolute ranges in force for a calendar day of the components along and perpendicular to the magnetic meridian and of the vertical component, the ranges in declination having been for this purpose converted into units of force of the component perpendicular to the magnetic meridian.

(*c*) The daily magnetic character figures, assigned according to the international scheme wherein " 0," " 1," " 2," respectively, denote quiet, moderately disturbed, and highly disturbed conditions.

(*d*) The daily values of temperature in the magnetic chamber.

Mean diurnal inequalities of H, D and V on " all " days and on international quiet and disturbed days are given, for the months, seasons and year, in Tables 53 to 61.

In calculating diurnal inequalities the non-cyclic change has been eliminated on the assumption that its time rate is linear. The values of the range of the mean diurnal inequalities of the several elements on the three different types of day are brought together in Table 62, and the values of the non-cyclic change are given in Table 64. The "Average Departures," or mean values of the inequality taken irrespectively of sign, throughout the 24 hours, are given in Table 63.

The mean values of the squares of the absolute daily ranges are summarized in Table 65.

In Table 66 appear for the months and year the mean values of N, W, V, D, I, H and Total Force T. The means of N, W, I and T are derived from the corresponding mean values of H, D and V, which are the means of hourly values on "all" days in the month or year.

Finally, in Tables 67 and 68 are given summaries of auroral observations obtained as already described.

Review of Results.

Mean and Extreme Values of the Magnetic Elements, 1929.—The mean values of the magnetic elements for the years 1928 and 1929 are given in Table I. The values of H, D and V have been computed from the hourly values derived from the autographic records of "all" days, standardized by means of the absolute observations; those of N, W, I and T have been deduced from the values of H, D and V.

TABLE I.

Year.	H.	D. (West)	I.	N.	W.	V.	T.
	γ	° ′	° ′	γ	γ	γ	γ
1928	14585	14 37·1	72 39·4	14113	3681	46702	48926
1929	14556	14 23·6	72 40·3	14099	3619	46651	48870

The decrease in westerly declination from 1928 to 1929 (13′·7) was greater than in the previous year (12′·8). The rates for the four years earlier were 13′·8 for 1923–24, 13′·0 for 1924–25, 14′·9 for 1925–26 and 12′·9 for 1926–27.

Mean values derived from (*a*) international quiet days and (*b*) international disturbed days, as follow:—(*a*) H, 14561γ; D, 14°23′·8; V, 46658γ; (*b*) H, 14549γ; D, 14°23′·7; V, 46646γ.

The extreme values of H, D and V recorded during 1929 are given in Table II., but these values may have been exceeded at times when the light passed beyond the edges of the photographic paper.

TABLE II.

Element.	Maximum.		Minimum.		Absolute Annual Range.
	Value.	Date, 1929.	Value.	Date, 1929.	
		d. h. m.		d. h. m.	
Horizontal Force ...	15242γ	Mar. 12 ... 15 25	<13265γ	Feb. 28 ... Between 1 3 and 1 8	>1977γ
Declination	16° 15′·5	Feb. 27 ... 21 51	12° 18′·2	Feb. 28 ... 1 5 1 8	3° 57′·3
Vertical Force ...	47095γ	Feb. 28 ... 0 50	46173γ	Feb. 27 ... 20 33	922γ

The range of 3° 57′·3 in declination is equivalent to a range of 1008γ in the component of force perpendicular to the magnetic meridian. In the year 1928 smaller ranges were recorded in H and D, but a larger range in V. In the year 1926 greater ranges were recorded in D and V, the extremes in these, respectively, having been > 4° 44′·9 and > 2086γ.

Magnetic character of the year.—The following table shows the mean sunspot numbers for recent years, together with the mean absolute daily range of declination, as a rough measure of magnetic activity :—

Year	1923	1924	1925	1926	1927	1928	1929
Mean Sunspot No. ...	5·8	16·7	44·3	63·9	69·0	76·8	64·2
Mean absolute daily range of D.... ...	14′·9	15′·4	18′·1	25′·0	20′·0	21′·4	24′·3

Coincident roughly with the increase in sunspots there was, up to 1926, an increase of magnetic activity, but the years 1927 and 1928 showed some falling away ; the year 1929, despite a fall in the sunspot number, now shows some recovery in magnetic activity. Although the next table shows no obvious relationship between the provisional sunspot numbers and magnetic conditions for the individual months of 1929, it appears from the data of a number of years that certain magnetic quantities, in the summer months, are fairly closely correlated with the sunspot numbers ; in the equinoctial months there is a small correlation and in the winter no very definite relationship emerges.

	Jan.	*Feb.*	*Mar.*	*April*	*May*	*June*	*July*	*Aug.*	*Sept.*	*Oct.*	*Nov.*	*Dec.*
Provisional sunspot number	65·4	61·9	52·8	52·8	57·6	72·2	70·1	62·1	34·7	54·7	81·2	105·1
Mean absolute daily range of D ...	17·3	38·4	30·2	19·0	18·1	19·3	23·0	22·2	23·3	30·5	24·3	26·5
Mean $\Sigma R^2/(100\gamma^2)$ ...	296	4215	1954	277	248	254	1025	929	532	1163	993	1001

The values of mean absolute daily range for the months and seasons of the year 1929 are given in Table IV., the ranges of declination in angle having, for convenience of comparison, been converted to units of force of the component perpendicular to the magnetic meridian. It will be seen that the ranges of H and V are greater than the corresponding Eskdalemuir values, the ratios of the annual mean ranges of Lerwick H to Eskdalemuir N, Lerwick D to Eskdalemuir W, and Lerwick V to Eskdalemuir V being respectively 1·5, 1·1 and 1·6 in 1929 ; the corresponding 1926 ratios were 1·4, 1·1 and 2·1 ; 1927 gave 1·3, 1·0 and 1·8 ; and 1928 gave 1·3, 1·0 and 1·1.

The significant change in the three years 1926-28 was thus a diminution in the ratios of the V ranges at the two observatories, whilst 1929 shows some recovery.

Another important change is in the seasonal behaviour of the ranges; at Lerwick during 1929 winter is the season of largest mean absolute daily range, whilst at Eskdalemuir equinox occupies that position.

The frequency distribution of absolute daily ranges recorded in 1929 is shown in Table V. A comparison with the corresponding figures for Eskdalemuir (Table V. on page 176) indicates that ranges in excess of 200γ are again much more frequent at Lerwick than at Eskdalemuir, even in the case of D or W ranges, of which the frequency distributions at the two places usually show less divergence. Apart from this it is notable that the ranges of maximum frequency at Lerwick again fall in the intervals 70-79γ for H, and 50-59γ for D, but 20-29γ for V, that is, at a lower point in the case of D than at Eskdalemuir, but at the same points in the cases of H and V.

TABLE VI.—PRINCIPAL MAGNETIC DISTURBANCES RECORDED AT LERWICK, 1929.

Where the beginning of a disturbance has been marked by a "sudden commencement," the serial number is followed by an asterisk (*), and the time entered in the second column is that of the sudden commencement, estimated to the nearest minute. In other cases, the exact hour nearest the time at which disturbance may be regarded as having begun is entered in the second column. To the tabulated values of maximum and minimum, the following have to be added :—H, 14000γ; D, 14°, V, 46000γ.

No.	From	To	Horizontal Force.					Declination.					Vertical Force.				
			Max.	Time.	Min.	Time.	Range.	Max.	Time.	Min.	Time.	Range.	Max.	Time.	Min.	Time.	Range.

Diurnal Inequalities.—The ranges of the mean diurnal inequalities of all days are about the same as those of 1928 in H and D, but much larger in V in equinox and winter.

The quiet day ranges are about the same as in recent years ; the mean inequality of H for the winter season, however, has a greater range than in the two previous years.

The ranges of the mean disturbed day inequalities for the year and winter season are greater in all elements than those of 1928 and 1927, but generally less than those of 1926. In the last four months of 1929 the ranges of the disturbed day inequalities are greater in V than in H, whereas in the first eight months, and also in nearly every month of 1928, they were less.

A comparison of the records of Eskdalemuir and Lerwick shows that the declination inequalities at the two places for all, quiet and disturbed days are very similar in general appearance, although minor irregularities on the one set of values are not always reproduced on the other, or, if so, only with diminished amplitude. Differences are more obvious on the horizontal force curves even on quiet days ; and the disturbed day inequalities in H in some months bear little resemblance to one another. In the case of vertical force the present year is the fourth year of observations to be published. In some months the quiet day inequalities are very different from those at Eskdalemuir, and it will be seen from the table below that the range of the inequality varies from about one-fifth of the Eskdalemuir range in August to 1·9 times the Eskdalemuir range in November. The seasonal variation of this ratio is thus higher than in any of the three previous years. At Lerwick the V oscillation on quiet days is more definitely semi-diurnal than at Eskdalemuir, having fairly well marked maxima at about 7h and 18h. In all seasons of 1929, as in 1928 and 1926, the afternoon hump is definitely the larger, though in 1927 the morning hump was rather the larger in the mean for the year and very definitely the larger in the summer season.

Ratio of the Range of the Inequality at Lerwick to that at Eskdalemuir. (1929).

On Plates I and II the diurnal behaviour of magnetic force is illustrated graphically, the representation in the latter plate being in the form of vector diagrams.

Magnetic Disturbances.—Particulars of the principal magnetic disturbances recorded at Lerwick during the year are given in Table VI. In the Eskdalemuir Section will be found a similar list which deals with the same disturbances as recorded at that Observatory.

In so far as " sudden commencements " are concerned it has to be remarked that within the limits of accuracy of measurement and registration, these events appear to occur simultaneously at the two Observatories.

Remarks on the Autographic Records, 1929.

January.—(Average Character Figure 0·35). After a quiet period at the beginning of the month a small disturbance began with a " sudden commencement " at 5d 3h 7m. The fluctuations increased during the evening hours, but were never large; a rise of 260γ took place in H between 19h 57m and 20h 8m, and was followed by an irregular fall to a minimum at 21h 10m, after which the disturbance died away. The ranges were :—H, 279γ ; D, 55′·8 ; V, 118γ.

Diurnal Variation of the Magnetic Elements

Lerwick 1929

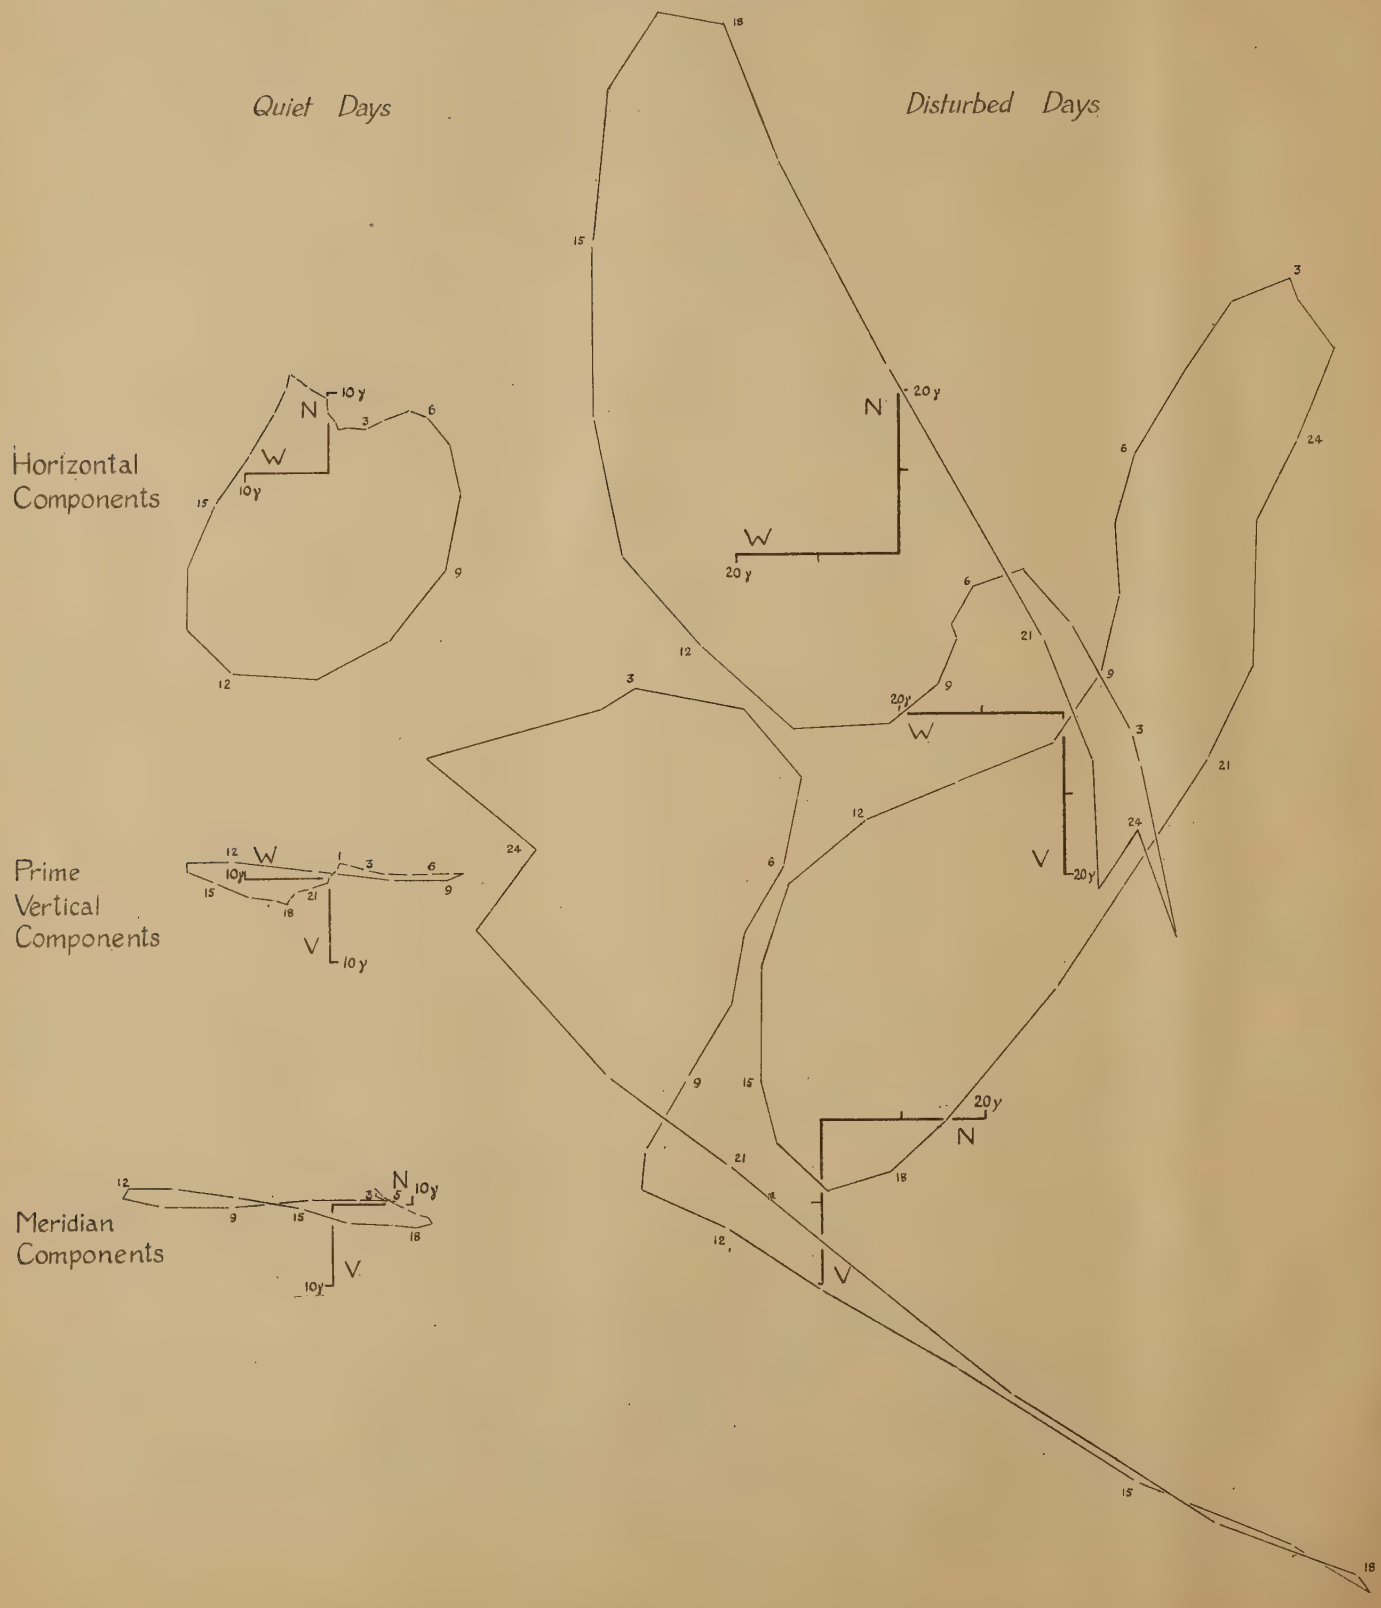
PLATE II.

VECTOR DIAGRAMS ILLUSTRATING DIURNAL VARIATION OF MAGNETIC FORCE

LERWICK 1929



At 8d 21h another disturbance began, during the course of which all three elements were almost continuously below their undisturbed values; after considerable fluctuations the minima occurred at practically the same time in all, viz., shortly before 9d 1h, and were followed by a rapid recovery in the case of H and D and a gradual rise in V. The disturbance died away at 4h, but was renewed to some extent at about 18h. The ranges during the 24 hours following the onset of the disturbance were: H, 603γ; D, 66′·0; V, 204γ, the first mentioned being three and a half times the corresponding N range at Eskdalemuir. There was considerable agitation during the 10th and the early hours of the 11th, after which conditions were very quiet for some 48 hours.

No other disturbance worthy of note occurred during the month; the period 17d 0h to 20d 8h was very quiet. A movement of the "sudden commencement" type at 20d 20h 48m was followed by agitation of a very slight nature, lasting some days.

Aurora was observed from one or more places in Scotland on January 2, 3, 4, 5, 9, 12, 15, 16, 28 and 30, but in no case was the display more than a glow, or widely seen.

February.—(Average Character Figure 0·82). The first half of the month was free from large disturbance, though few days were entirely quiet; the quietest period was from about 3d 14h to 5d 2h. Considerable agitation took place on the afternoon of the 6th, and it was a week before conditions became calm again. Small dips occurred in D at about 6d 19h and 23h, the latter accompanied by a small hump in H; a peak of 120γ occurred in H around 8d 20h, accompanied by a hump of some 200γ in V; apart from these movements there was nothing worthy of description. A "sudden commencement" at 12d 19h 36m was followed by disturbance too slight for remark.

After a comparatively quiet interval from the 13th onwards, a disturbance, which eventually became very large, began at 16d 15h 7m. The oscillations were at first small and rapid, but larger fluctuations set in soon after 23h, with a rapid rise and fall of 90γ in H, a drop of 9′ in D and a dip of 75γ in V. Shortly before 17d 4h H fell rapidly by 60γ, while D rose by 25′ to a sharp peak; thereafter the fluctuations became more violent, until the storm attained its greatest intensity on the afternoon of the 17th and the succeeding night. H mounted rapidly but irregularly during the afternoon, reaching its maximum in an abrupt peak shortly before 16h; after large fluctuations lasting an hour, H began at 17h 0m a rapid fall of 275γ in 10 minutes. Between 17h 30m and 18h there was a rapid rise and fall of some 330γ, and this was succeeded by a temporary decrease of activity in all three elements lasting about 2¼ hours.

The movements in D and V corresponding to those of H described above were irregular and not of very large extent. Both D and V were most active from 15h to 18h; mention may be made of a sharp dip of 45′ in D with minimum at 17h 3m, and a drop of 33′ at 18h, followed by a smaller rise.

Disturbance was renewed suddenly at 20h 24m, when H, D and V fell abruptly by 400γ, 43′ and 280γ respectively. The fluctuations were very violent until about 23h and rather less so after that; all elements were below their undisturbed values until 18d 5h, apart from a few sharp peaks in D. Soon after 17d 23h a rapid rise took place in H; D and V continued to fall, but with smaller fluctuations. D reached a minimum at 18d 1h 12m, and rose rapidly to a rounded hump at 2h, followed by another at 3h 20m; the minimum of V occurred at 3h 30m and was followed by a gradual rise till 6h.

The ranges in the period discussed were:—H, 1367γ; D, 101′; V, 460γ. The The disturbance was practically at an end at 18d 5h, but was renewed at 23h. H rose to a small hump soon after midnight and began to fall at 3h 15m on the 19th; the fall reached a depth of 160γ at 4h 10m and was followed by an irregular rise for 3 hours. Two dips of some 13′ occurred in D with minima at about 0h 30m and 1h 45m. V fell slowly till 3h, afterwards rising again.

There was considerable agitation during the succeeding days, and another small disturbance began on the afternoon of 21st, and became more conspicuous on the 22nd. There was a small outburst of activity around 22d 16h 30m, but the largest fluctuations began at 20h 21m, with a sharp rise of 50γ in H; this was followed at 20h 40m by a fall of 110γ in 16 minutes. Concurrently with these movements several oscillations of moderate amplitude took place in D. There was further activity around 23h, when the minimum of H occurred. V was below its undisturbed value from 22d 21h to 23d 4h.

After 23rd conditions became quiet for a space, but a minor disturbance took place during the night of the 25th. After small and rapid oscillations beginning at 25d 18h, H began to fall shortly before 22h, reaching a depth of 185γ below the undisturbed value at 22h 39m; a rapid recovery followed, the whole movement forming a symmetrical V-shaped depression, ending at 23h 30m. D rose to a maximum at 22h 35m and fell by 28′ to a minimum at 23h 20m. V rose to a rounded maximum at 19h; at 22h the fall became more rapid and a minimum was reached at 22h 35m, the range being 186γ. Disturbance was considerably greater on the next night, following a "sudden commencement" at 26d 19h 22m, and very much greater on the night of the 27th–28th. After a small peak at 26d 20h, H was below its undisturbed value from 21h to 6h of the 27th. The greatest activity in all elements began at 26d 23h with a large and rapid fall in H, and ended at 2h with a rapid rise in H; thereafter the fluctuations, though large in D, were not of such extreme rapidity, but were rather of the character of humps and dips superposed on oscillations of very small period and amplitude. In a qualitative sense this description would apply to most magnetic storms at Lerwick.

There was a rather sudden cessation of activity at 27d 7h 45m, and conditions were comparatively quiet till 14h, when a very large disturbance began. H mounted irregularly to a series of sharp peaks around 19h; there was also a large peak at 15h 47m. D oscillated without any great change till about 18h 20m, when it rose to a very sharp peak at 18h 42m. V increased gradually till 18h. Between 18h 38m and 52m a remarkable movement took place in H, consisting of an abrupt fall of 540γ, followed by a complete recovery; the minimum occurred at 18h 44m. A large oscillation took place in V, which fell to a minimum at 18h 40m and rose by 270γ to a sharp peak at 18h 47m.

Between about 19h and 20h 30m H fell by some 900γ or 1000γ in three abrupt stages. Between 20h 22m and 30m D fell by 130′ rising by 165′ in the next 7 minutes. V fell by 475γ between 20h 22m and 33m. From this time until 28d 3½h the disturbance in all elements was at its height. Innumerable fluctuations of the order of 1° took place in D. V fluctuated rapidly and irregularly; a sudden maximum was reached at 28d oh 50m, shortly before pronounced minima in H and D, after which H rose very rapidly, and the amplitude of the oscillations began to decrease. At about 3h 30m D began to rise, reaching an approximately normal value at about 4h 20m; the rise in H ended at 4h, after which the oscillations were of small period and amplitude. The ranges during the night of the 27th–28th were:—H, > 1885γ; D, 237′ (nearly 4°); V, 922γ.

On the afternoon of the 28th there was a temporary renewal of disturbance. Between 12h and 14h 7m H rose by some 270γ to a sharp peak, falling again during the next hour; at about 14h there was an abrupt dip of some 12′ in D and minor activity in V.

Aurora was observed from one or more places in Scotland on February 8, 9, 10, 17, 18, 26, 27 and 28. The display of 27th–28th was striking and was widely observed even as far south as the south coast of Devonshire. Unusual night visibility was re-

ported by S.S. Marella* on February 26th on a voyage between Australia and Java. Between 2 a.m. and 3 a.m. on that date Mt. Cheremai (10,099 ft.) was visible to the naked eye when the ship was at distances ranging from 55 to 61 miles.

March.—(Average Character Figure 1·00). The first disturbance to be noted was a minor one lasting from the afternoon of the 7th till the end of the 8th. The movements were not large and consisted mainly of small and rapid oscillations throughout nearly the whole period. The disturbance began at about 7d 17h 25m with a dip of 20′ in D and a small rise in V. H was below its undisturbed value from 7d 21h to 8d 3h; both H and V rose during the afternoon to a maximum at 16h, after which the disturbance died away. There was a temporary renewal of activity from 20h to 21h, D making a dip of 30′.

A "sudden commencement" at 11d 13h 53m marked the beginning of a large disturbance. In its general outline this followed the usual course, but the range of V was unusually small compared with that of H; moreover, the period of greatest activity, with very low values of H, was later than usual on the first night of the storm, viz., between 2h and 8h on the 12th. After this H rose rapidly and from 13h to 19h underwent many large fluctuations. A notable feature consisted of a series of peaks in D at 12d 10h 40m, 13h 6m, 15h 26m, 17h 57m, 20h 22m, 22h 44m and about 13d 1h 10m; of these the middle three are very sharp and narrow peaks some 60 or 70′ high, the others being less well defined; the intervals are very nearly 2h 25m. (It will be observed that the maximum of D for the 12th, at 5h 43m, fits this series fairly closely. There was also a small peak at 12d 0h 57m). From 12d 19h to 13d 6h there was a large dip in H accompanied by rapid oscillations, and the minimum of H for this night occurred in a sudden drop at about 22h 30m.

The movements of V consisted of a gradual rise on the afternoon of the 11th until 17h, followed by a gradual fall. Between 3h and 7h on the 12th there was considerable activity, though the movements were not large. V rose somewhat during the morning, but there were no well-defined movements during this day, the fluctuations being comparatively small and irregular. Slight increases of activity in V were associated with most of the above-mentioned peaks in D. The ranges between the onset of the storm and the morning of the 13th were:—H, 1646γ; D, 139′; V, 415γ. The H range is some five and a half times as great as that recorded at Abinger.† The disturbance died away after 13d 6h.

Another large disturbance began on the morning of the 15th. Conditions were fairly quiet until 13h, after which H rose rapidly, reaching a maximum at 16h 55m; the fall after the maximum was very large and rapid and was followed by a quiet interval from 17h 40m till 19h 50m. In V there was a hump from 15h to 20h, with a small dip at the time of the maximum of H; in D the oscillations were small and irregular. At 20h the disturbance was renewed. H fell by some 200γ at about this time, and soon after midnight another larger fall marked the beginning of the most disturbed period, which ended at about 16d 3h 30m with a rapid rise of H. The disturbance then died away, but there was minor disturbance during the next 24 hours and some activity for several days afterwards.

A small disturbance occurred during the night of the 20th-21st. The most noteworthy feature was a sharp dip of 360γ in H between 21d 3h and 4h, followed by an irregular dip between 5h and 8h.

During the rest of the month conditions were moderately quiet, though no day was free from minor activity.

*Marine Observer, VII., p. 42.

†Nature, 123 (1929), p. 504.

Aurora was observed from one or more places in Scotland on March 2, 3, 4, 6, 7, 8, 11–17, 22, 25, 27, 29 and 31. The display of March 12th was bright and widely observed. Ships in various seas reported bright aurora at about this time, viz., : on March 11 at 9 p.m. in lat. 51° 41′N, long. 144° 12′W, on March 12 off New Zealand coast in 40°S lat., on March 12 at 11.30 p.m. in lat. 37°48′S, long. 129°55′E, on March 11 at 10 p.m. in lat. 49°10′N, long. 134°40′W.*

April.—(Average Character Figure 0·77). There were very few disturbances this month, and none of large magnitude.

A "sudden commencement" at 4d 9h 27m was followed by small and rapid oscillations for about 9 hours, but no magnetic storm developed. Conditions were then quiet for eleven days, especially during the hours from 9d 20h to 10d 11h.

At 15d 16h considerable agitation began; there were, however, no large movements until 16d 3h 5m, when H began to fall rapidly. The fall reached a depth of 340γ at 3h 42m and a rapid rise followed. There was a peak of about 25′ in D at 3h 51m. Superposed on these movements in H and D there were very rapid oscillations of small amplitude from about 3h 30m to 4h 30m. There was a dip of 130γ in V from 1h till 8h, with a small peak at 3h 45m.

During the morning and afternoon of the 16th small rapid oscillations continued in H and D. The afternoon rise in H was broken by a small hump between 14h and 15h, and continued until the maximum was reached shortly after 17h. At 22h 34m greater disturbance set in with a fall in H and V, and a rise in D; the dip in V and large fluctuations in H and D continued from then until 17d 2h, when a rapid rise in H marked the end of the major disturbance. H and V continued to rise for another three hours. There was agitation, though of diminishing degree, during the next 48 hours.

Nothing worthy of note occurred from this time until the last three days of the month. The 20th was a very quiet day.

On the 28th day there was renewed activity, which continued for a further five days. The fluctuations were for the most part rapid and irregular, but not of large extent; on the afternoon of the 29th, however, the normal diurnal variation of H was somewhat accentuated, and between 21h and 22h there were one or two well-marked smooth oscillations in both H and D.

Aurora was observed from one or more places in Scotland on April 1, 2, 4–11, 16, 20, 21 and 30, but in no case widely. It is reported as having been seen from S.S. Wellington in lat. 38°12′S, long. 138°58′E on April 16, 13·20 to 13·40 G.M.T.†

May.—(Average Character Figure 0·67).—There was continuous minor activity during the first three days; conditions were then quieter until after the occurrence of a "sudden commencement" at 11d 23h 10m. From the 12th till the 17th inclusive there was considerable agitation, which reached the extent of a small disturbance on the 13th. On this day V began to fall at 3h, reaching a minimum, 180γ below its undisturbed value, at about 4h 40m. H and D fluctuated irregularly, H being slightly below its undisturbed value from 2h till 6h. In the three hours from noon H rose irregularly by some 240γ to a maximum at 14h 42m; between 15h 10m and 15h 40m a drop of 120γ occurred, and was followed by an irregular hump till 19h. Small dips of the order of 15′ took place in D at about 14h 30m, 17h 40m and 20h 20m. V rose rather rapidly between 13h and 13h 40m, continued at about the same value till 17h 37m, when the maximum occurred in a small peak, and then fell gradually for about 5 hours. The ranges during the period discussed were :— H, 281γ; D, 34′·8; V, 286γ.

*Marine Observer, VII, p. 65. †Marine Observer, VII, p. 82.

A second spell of disturbance is regarded as commencing about 14d 12h. At 14d 20h 40m a rapid drop began in D ; a minimum 26′ below the undisturbed value was reached at 21h 12m, and was followed by a rapid recovery and a few small oscillations. Slight activity occurred simultaneously in H and V. On the following night (15th-16th) there was some activity from 20h to 22h, and a sharp dip of 150γ in H between 2h 30m and 4h 30m.

From the 18th to 24th inclusive conditions were fairly quiet, with the exception of the hours from 4 to 16 on the 23rd. Between 23rd 5h 30m and 6h 30m, H fell by 95γ, and there was a hump of 12′ in D from 6h 30m till 7h 50m and a small rise and fall of V between 6 and 7h. During the next eight or nine hours the movements were small and rapid.

Towards the end of the 24th conditions became more disturbed again, and considerable movements took place in the early hours of the 25th. On the afternoon of the 28th there was a small disturbance, preceded for several hours by small and rapid oscillations. A drop of 120γ in H soon after noon was followed by an irregular rise to a maximum in a peak at 16h 45m ; H fluctuated near this value for three hours, and the disturbance ended rather suddenly with a fall of 38γ shortly before 20h. D rose to a maximum at 15h, afterwards falling gradually till 20h. Small rapid oscillations were present all the time, but there were no large movements ; between 19h and 20h an oscillation with a range of 7′·5 marked the end of the disturbance. The only noticeable movement of V was a small hump around 16h. There was some activity from 9h till 21h on the 30th.

Aurora was not reported from any place in Scotland during May.

June.—(Average Character Figure 0·70).—There was a considerable amount of minor disturbance in this month, but none of large dimensions. After slight activity during the first three days conditions were moderately quiet until the morning of the 8th ; from then till the end of the 12th disturbance was practically continuous, being greatest on the 10th and 11th. On the afternoon of the 8th there were two small humps in H around 14h and 17h, followed at 22h by a rapid rise of 30γ and a fall of 85γ in the next 50 minutes. There were small dips in D and V between 8d 22h and 9d 2h. The 9th was more disturbed, and after 20h there were considerable irregular fluctuations in D, which continued during the 10th and until the early hours of the 11th. A sharp dip of 100γ occurred in H between 10d 5h 30m and 7h ; H rose during the afternoon until soon after 17h and then fell irregularly until midnight. In V there was a rounded maximum between 17h and 18h followed by a gradual fall to a minimum at 11d 1h. After a hump of some 70γ in H around 11d 1h fluctuations in all elements were small but rapid until the afternoon, when H rose to its maximum at 16h 30m. From then the movements were very small until 19h 44m, when there was a fresh outburst of activity which lasted until nearly 22h ; V dipped slightly, while H and D made several irregular oscillations.

Disturbance was considerably less on the 12th, and the period 13d 22h to 15h 6h was very quiet. Normal conditions prevailed for the next few days. Some fresh disturbance was manifest from 21d 12h and much agitation on the 22nd–24th. Between 23d 8h and 24d 8h the oscillations were very rapid in H and D, though the ranges were not large. The activity was greatest between 13h and 19h, during the afternoon rise in H, and again around 22h.

The remainder of the month was normal, apart from the afternoon of the 28th. On this date the diurnal oscillation of H was magnified into a large hump, roughly 150γ higher than the undisturbed value, between 12h and 20h. Between 14h and 17h there was activity of a small order in all elements.

Aurora was not reported from any place in Scotland during June.

July.—(Average Character Figure 0·84). A small disturbance began on the morning of the 5th. The usual afternoon activity in H in a storm was represented by a small hump between 15h and 17h; the maximum occurred at 16h 30m and was followed by a rapid drop of 150γ. The maximum of D occurred simultaneously with that of H, in a small peak 8′ high; at about 16h 38m, when the fall in H and D became most rapid, V began to rise, and at the time of maximum, some half-an-hour later, had risen by 90γ. No other noteworthy movements took place until the following morning, when there was a dip of 95γ in H between 5h and 7h, and a hump of 15′ in D; between 6h and 9h V dipped by 70γ.

The next disturbance began on the morning of the 10th. H fell gradually from 6h till 7h 30m, but there were no large movements until 11h 34m, when H rose abruptly by 195γ; there were also small movements in D and V. After this the activity was much greater, and there were several large peaks in H during the afternoon and evening; the maximum of H occurred in a very sharp peak at 16h 49m, and there was a small peak in D at about the same time. 16h 45m was the beginning of a rounded hump in V, which reached a maximum after a small temporary dip at 18h, and then fell irregularly until midnight. At 21h 19m there was a sudden outburst of activity, which resulted in a large oscillation in all elements. H rose by 260γ to a very sharp peak at 21h 24m, fell by 530γ in the next 12 minutes, and rapidly recovered to nearly its original value. The movement in D consisted of an irregular rise of 27′ to a maximum at 21h 34m, followed by a rapid fall. V, after a small rise, fell by 270γ to a minimum at 21h 30m. A large dip of some 380γ occurred in H, beginning at 22h 23m and ending at 23h 40m after a rapid rise; there was a small peak of 20′ between 22h 23m and about 23h, followed by several irregular oscillations until 23h 40m, when the disturbance came to an end, except for minor fluctuations. The ranges were: H, 864γ; D, 47′·6; V, 430γ.

Another disturbance began with a rapid rise of 35γ in H at 14d 16h 31m, but no large movements took place until shortly before midnight. After its initial movement, H continued to rise gradually, reaching a maximum at about 18h. Shortly before 20h there was a hump of 38γ in H, a dip of 18′ in D and a hump of 45γ in V; during the next three hours, which were quiet, H fell gradually. About $\frac{1}{2}$ hour before midnight H began to fall rapidly, and there was increased activity in D and V. H reached its minimum at 15d 0h 37m in a very sharp dip, and immediately rose rapidly; between midnight and 3h there was great activity of a small order in H and D superposed on the larger fluctuations. D fell to a minimum at 2h 30m, and there was a small dip in H at the same time; H and D then rose rapidly and made many large fluctuations before 5h. V began to fall at about 1h and there was a dip of some 200γ until 7h. The ranges during this period were: H, 298γ; D, 64′; V, 383γ.

During the morning and afternoon of the 15th there were continued small and rapid oscillations and at 17h the disturbance broke out again. Some of the features of the previous night were reproduced. There was no great activity at first; H rose to a maximum at 18h, and then fell gradually but with increasing velocity; there was a small peak in D shortly before, and a small rounded maximum in V shortly after, 18h, and conditions were then quiet until after 22h. At about 22$\frac{1}{2}$h the fall of H became very rapid and the trace passes beyond the limit of registration at 23h, reappearing some half-hour later, when H was rising at a great speed. Between 23h 0m and 1om there was a sharp dip of 23′ in D, followed by a peak at 23h 26m and a drop of 85′ to a minimum at 23h 59m. Small and rapid oscillations were continuous throughout this period. V began to fall rapidly at 22h 57m, reached a minimum at 23h 13m, and oscillated irregularly until midnight; V was below its undisturbed value from 15d 22h till 16d 2h.

H continued its rapid rise until 16d 1h, when it reached its normal value, and the disturbance was temporarily at an end.

The ranges between the afternoon of the 15th and the morning of the 16th were : H, < 672γ ; D, 85′ ; V, 390γ.

Disturbance was renewed on the afternoon of the 16th, and in this case was over before 22h. The maximum of H occurred in a very tall peak at 15h 8m, and was followed by an irregular fall broken by large fluctuations. There was considerable activity in D between 14h and 20h ; the maximum was reached at 16h 31m, and there was a rounded hump at 18h, and another preceded the drop to a minimum at 20h 0m. V reached its maximum soon after 15h and fell gradually until 2h the next morning. On the following afternoon there was a small outburst of activity between 11h and 14h.

During the rest of the month the degree of activity was fairly constant. On the afternoon of the 24th there was a slight disturbance ; from the 27th onward conditions were quieter until the end of the month. A disturbance began in the last hours of the 31st and will be described under August.

Aurora was not reported from any place in Scotland during July.

August.—(Average Character Figure 0·74).—At 21h 6m on July 31st there was a sudden rise of 58γ in H, a small rise in D and a small drop in V. Considerable agitation followed, and developed into a large disturbance during the night of August 1st–2nd. During the morning and afternoon of the 1st there were many small and irregular fluctuations, superposed on the normal diurnal variations, which were somewhat enhanced. Soon after 22h H began to fall very rapidly and this was, as usual, the beginning of the most disturbed period of the storm, H and D oscillating very rapidly during the next hour. H reached its minimum a few minutes before 23h ; after a sharp peak at 23h 7m it rose rapidly and attained a normal value before midnight. D rose to a double peak with maxima at 23h 5m and 23h 16m, and then fell to a minimum at 23h 41m. There was an irregular peak in V, some 160γ high, between 22h 30m and 23h 16m. In the two hours after midnight there was a temporary cessation of disturbance, but it was renewed soon after 2d 2h with a fall of 260γ in H and further rapid oscillations about the time of minimum (3h 20m). H rose again immediately, and the disturbance was practically at an end by 5h ; there was a dip of about 90γ in V between 2 and 5h. The ranges were : H, > 562γ; D, 54′·8 ; V, 284γ.

A small disturbance took place on the night of the 4th–5th. D made several fairly regular oscillations of roughly 6′ amplitude between 4d 23h and 5d 3h, but the greatest activity occurred between 1h and 3h during a dip of 150γ in H ; there was a shallow dip in V from midnight to 4h.

From the 6th to 13th inclusive conditions were quiet, apart from an outburst of activity of a small order from 0h to 23h on the 11th.

A disturbance, which became very large during the afternoon and night, began at 14d 12h 27m with small movements in all elements. The disturbance followed a normal course in its main features. All three elements were at their highest values about 18h. H then fell rapidly, and there was very great activity during two deep dips in H, the first shortly before 22h and the second from 23h to 15d 2h. The ranges were : H, 1041γ ; D, 80′·1 ; V, 349γ.

During the 15th–20th inclusive there was slight disturbance and the rest of the month was comparatively quiet.

Aurora was seen from one or more places in Scotland on August 2 and during the night of 14th–15th.

September.—(Average Character Figure 0·87).—There was no large disturbance this month, but disturbance of moderate degree occurred on about ten days.

Quiet conditions continued until the end of the 6th, when a small movement in all three elements marked the beginning of a disturbance which lasted for 24 hours, with ranges of 166γ in H, 49′ in D, and 296γ in V. After a small peak shortly before 7d 1h, D made a dip of 36′ between 2h and 7h; several small dips occurred in H, while V was below its undisturbed value from about 1h to 7h. H fell to a minimum at 10h, rose gradually to a maximum at about 17h, and fell again slowly: small oscillations were present continuously. Between about 15h and 16h D fell by 15′ and V rose by 105γ; the return to the former values took place in each shortly before 21h.

Slight disturbance set in again rather suddenly about 8d 21h 14m; about 24 hours later, viz., at 9d 21h 27m, more marked disturbance set in and this continued until the 15th. At 10d 17h 29m a value of 14706γ was attained in H and a few minutes later D fell to 13° 56′·5. The lowest value of H, 14359γ, was attained at 11d 1h 27m in a "pit" between midnight and 2h of 11th. The successive daily traces over the period 8th to 15th show frequent apparent repetitions of movements.

Quiet conditions ensued until the afternoon of 21st, when moderate disturbances again became evident. The most outstanding movements in this storm were two "pits" in H, one around 1h and the other around 4h of 22nd. The minimum value (14225γ) was attained in the former at 22d 1h 1m. This disturbance died down about 22d 22h, the remainder of the month being marked by no noteworthy movements, though 27th was slightly disturbed.

Aurora was seen from one or more places in Scotland on September 3, 5, 9, 10, 12, 13, 14, 22, 27, and 30.

October.—(Average Character Figure 0·94). The quietness characterizing the latter part of September was maintained until the early hours of 7th October, when a moderate disturbance was ushered in by a period of small vibratory movements. The only notable movement in this disturbance was a sharp rise in D to 15° 6′·5 at 7d 22h 13m. Conditions were not entirely quiet again until the evening of 13th. After two very quiet days the largest disturbance of the month was ushered in by a "sudden commencement" at 16d 11h 14m. In a sharp rise commencing at 16d 17h 45m, H increased by some 170γ to a maximum of 14821γ at 18h 6m, falling again by 360γ in a further five minutes; again in a sharp movement setting in about 20h 32m it fell by nearly 500γ to a minimum of 13990γ at 20h 54m, and had recovered by 580γ at 23h 18m. The movements in declination were somewhat similar but (interpreted in units of force) of about half the magnitude. The abrupt movements in V were in the opposite sense to those in H and D, and of a total range of 557γ, as against 831γ in H. The evening of 17th showed a roughly approximate repetition, about 1½ hours later in time, reduced in the case of H to about three-fourths of the range and considerably more flattened in the case of D; whilst in V the movements were now in the same direction as in H. Yet again, in the more rapid movements, the night of 18th–19th shows a suggestion of a repetition, modified and delayed by a further 2½ or 3 hours, of the sharp movements of the two previous evenings.

From the 21st inclusive conditions were fairly quiet until 30th, when a period of slight disturbance commenced.

Aurora was seen from one or more places in Scotland on October 3, 7–10, 12, 14, 17, 23–27, 29–31. On 7th, 8th and 30th the display was observed fairly widely.

November.—(Average Character Figure 0·83).—The slight disturbance noted at the end of last month continued into November; following a small movement, rather like a "sudden commencement," at 2d 12h 57m, greater disturbance supervened, more particularly within the period 2d 20h to 4d 4h. A notable feature of the H trace on the afternoon of 3rd is a succession of sharp peaks at 15h 3m, 17h 0m and 19h 17m, at which times maxima of 14735γ, 14773γ and 14826γ, respectively, were attained. Corresponding depressions occurred in D at 15h 15m, 17h 8m and 19h 20m, with minima of 13° 32′·5, 13° 28′·6 and 13° 33′·5 respectively.

A "sudden commencement" at 8d 21h 43m was followed by no disturbance worth mention, conditions remaining very quiet from the 8th until the evening of the 15th. Thereafter slight disturbance ensued at first, but between 14h and 22h of 16th, and more particularly between 18h and 21h, extremely rapid movements of considerable range were in progress. The ranges reached within the three hours amounted to 774γ in H, 65′·1 in D and 285γ in V. The disturbance subsided with remarkable rapidity about 22h and was followed by three days of very small variation in force. Shortly before 20d 12h some indication appeared of another disturbance. The chief feature was a very considerable afternoon hump in which H and V rose 200γ above their undisturbed levels; the quick return to fairly quiet conditions and the absence of any corresponding dip around or after midnight made the afternoon rise the more remarkable. Conditions were afterwards fairly quiet for the rest of the month and particularly quiet about 23rd to 25th.

Aurora was seen from one or more places in Scotland on November 1–3, 5, 6, 8–10, 12, 14–16, 20, 24, 26, 27 and 30.

December.—(Average Character Figure 0·90). The month opened with quiet conditions, the first considerable disturbance developing gradually from about midday of 3rd. This disturbance possessed no very notable features, but lasted a considerable time, diminishing gradually after the 6th. The most abrupt excursion in H was a dip of some 250γ between 4d 0h 40m and 1h 25m.

Conditions had not become entirely quiet when some further disturbance of a minor nature set in on 11th, lasting for about a day. The 13th, 14th and 15th were rather quieter, but on 16th there commenced the chief disturbance of the month. On the afternoon of that day H rose some 450γ and V some 250γ above their undisturbed levels. In the case of H, as in the storm of 20th November (26 days earlier), there was the peculiarity of no corresponding subsequent dip; in V there was a dip just after 18h, but no important movements later in the night. In both the D and the H traces of this day there are other points of resemblance to those of 20th November. There was some repetition of disturbance on a lesser degree on the following afternoon.

The 19th to 21st was the quietest period of the month. Shortly after 21d 22h small oscillations set in suggestive of fresh disturbance, which indeed developed on the following day. The chief movement was a rise in H of about 200γ in the half hour ending 22d 17h 40m, when a value of 14775γ was attained.

The 26th and 27th were quiet, and the remainder of the month had no disturbance worthy of mention.

Aurora was seen from one or more places in Scotland on December 1, 3–6, 8–10, 16, 22–24, 26, 27, 29–31.

POTENTIAL GRADIENT (reduced to level surface): VOLTS PER METRE.

NOTE.—The Potential Gradient is reckoned as positive if the potential increases upwards. For indeterminate potential gradient the following notation is used: z +, Indeterminate, positive value; z—, Indeterminate, negative value; z ±, Indeterminate in magnitude and sign.

(*a*) Mean of all positive readings. (*b*) Mean from all complete days using both positive and negative readings.

Mean Values for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

The Potential Gradient is reckoned as positive if the potential increases upwards. For indeterminate potential gradient the following notation is used: z+, Indeterminate, positive value; z−, Indeterminate, negative value; z ±, Indeterminate in magnitude and sign.

(*a*) Mean of all positive readings. (*b*) Mean from all complete days using both positive and negative readings.

POTENTIAL GRADIENT (reduced to level surface) : DIURNAL INEQUALITIES (in volts per metre).

The departures from the mean of the day are adjusted for non-cyclic change.

* 0*a* DAYS ONLY.

Annual Values:—Character Frequency	104	186	72

Mean character figure 0·91 (362 days)

Duration of negative pot. grad.: Total 528·3 hrs.
No. of days 341
Mean 1·55 hrs.

Explanatory Note.—The electrical character of the day is indicated by the figures 0, 1, or 2, according to the character of the trace of the electrograph as regards negative potential gradient. The explanation of these symbols is as follows:—

0, denotes a day during which from midnight to midnight no negative potential was recorded.

1, denotes a day with excursions to the negative not amounting in the aggregate to more than three hours.

2, denotes negative potential extending in the aggregate over 3 hours or more.

a, denotes that within the 25 periods of 60 minutes for which an estimate of the mean potential gradient has to be made in the process of tabulation there was in no case a range of potential gradient in the open exceeding 1000 volts.

b, denotes that a range of potential gradient in the open exceeding 1000 volts was reached in at least one but in fewer than six of the 25 hourly periods referred to above.

c, denotes that a range of 1000 volts or more occurred in at least six of the 25 hourly periods.

Mean values for periods of sixty minutes centred at the hours of Greenwich Mean Time.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56–61.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

7. Lerwick (V.) 46,000 γ (·46 C.G.S. unit) + **January, 1929.**

§ For explanation *see* p. 32. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56–61.

TERRESTRIAL MAGNETIC FORCE: HORIZONTAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

Q denotes an " International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56–61.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

23. Lerwick. (V.) 46,000 γ (·46 C.G.S. unit) + May, 1929.

Q denotes an " International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56–61.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

27. Lerwick. (V.) 46,000 γ (·46 C.G.S. unit) + **June, 1929.**

§ For explanation *see* p. 32. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56–61.

TERRESTRIAL MAGNETIC FORCE: HORIZONTAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

Q denotes an " International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56–61.

TERRESTRIAL MAGNETIC FORCE: VERTICAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

31. Lerwick. (V.) 46,000 γ (·46 C.G.S. unit) + **July, 1929.**

Q denotes an " International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56–61.

TERRESTRIAL MAGNETIC FORCE: VERTICAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

§ For explanation *see* p. 32. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56–61.

TERRESTRIAL MAGNETIC FORCE: HORIZONTAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

§ For explanation *see* page 32. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56–61.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56-61.

TERRESTRIAL MAGNETIC FORCE : VERTICAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

51. Lerwick. (V.) 46,000 γ (·46 C.G.S. unit) + **December, 1929.**

* Clock stopped. † Mean of 30 days; 14th omitted.

§ For explanation *see* p. 33. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 56–61.

DIURNAL INEQUALITIES OF THE TERRESTRIAL MAGNETIC ELEMENTS.—"ALL" DAYS.

Departures from mean of the day adjusted for non-cyclic change.

HORIZONTAL FORCE (*all days*).

67. Lerwick. 1929.

Date.	Month.
	January.
1 ..	Mainly fair.
2 ..	
3 ..	Cloudy to overcast.
6 ..	Cloudy to overcast, rain.
7 ..	Cloudy to overcast, rain.
8 ..	Cloudy to overcast, rain.
10 ..	Cloudy to overcast.
11 ..	Overcast, 21·00–22·00.
12 ..	Cloudy to overcast, rain, 20·57 21·43.
14 ..	Cloudy to overcast, rain, 19·00–20·25.
15 ..	Moonlight, snow showers.
16 ..	Moonlight, cloudy, snow showers.
18 ..	Moonlight, mainly cloudy.
19 ..	Overcast, 19·00–21·25.
21 ..	Moonlight, fair to cloudy.
22 ..	Moonlight, cloudy.
23 ..	Moonlight, fair to cloudy.
24 ..	Moonlight, cloudy.
25 ..	Moonlight, fair to cloudy.
26 ..	Moonlight, cloudy.
27 ..	Moonlight.
	February.
4 ..	Cloudy to fair.
5 ..	Mainly fair.
8 Ш	Faint aurora, 19·00–00·10.
9 Ш	Glow, 19·00–20·00 eclipsed by cloud ; faint glow visible through breaks in clouds, 24·00–01·00.
11 ..	Cloudy to overcast, snow showers.
12 ..	Overcast 19·18–21·00, snow and sleet.
13 ..	Mainly cloudy, snow showers.
14 ..	Fair to cloudy, moonlight, snow showers.
22 ..	Moonlight, cloudy.
24 ..	Cloudy, hail showers, moonlight.
25 ..	Cloudy.
26 Ш	Glow visible through breaks in clouds, 19·45–21·20.
27 ..	Mainly cloudy.
28 ..	Overcast to cloudy, 19·00–20·06.
	March.
1 ..	Overcast, 20·24–22·20.
2 ..	Mainly cloudy.
3 Ш	Glow, 21·15–22·20.
4 Ш	Glow visible through breaks in clouds, 19·19–20·00.
6 ..	Cloudy to fair, overcast 22·30–23·50.
7 Ш	Overcast to 23·30. Glow visible through breaks in clouds, 24·00–01·15.
8 Ш	Glow visible through breaks in clouds, 20·25–21·00 and 01·45–02·30.
9 ..	Overcast, 20·45–24·00.
10 ..	Mainly fair.
11 Ш	Glow visible through breaks in clouds, 20·00–20·40 and at 21·59.
12 Ш	Aurora observed 19·40–03·00.
13 ..	Overcast, 19·43–22·21, showers.
14 Ш	Glow visible through breaks in clouds, 22·15.
15 Ш	Aurora observed 19·45–21·41.
16 ..	Cloudy.
18 ..	Moonlight.
19 ..	Cloudy.
22 ..	Moonlight, fair to cloudy.
24 ..	Moonlight, fair to cloudy.
27 Ш	Faint aurora visible through breaks in and above bank of cloud, 20·30–21·30.
30 ..	Overcast, 20·23–24·00.
31 Ш	Faint glow visible through breaks in clouds, 21·55–23·05.
	April.
1 Ш	Faint glow, 22·01–22·30, arch 23·00.
2 Ш	Faint glow through breaks in clouds, 21·00–22·14.
3 ..	Mainly cloudy.
4 Ш	Faint aurora visible through breaks in clouds, 22·33–22·48.
5 Ш	Faint glow visible through breaks in clouds, 21·38–23·00.
6 ..	Mainly cloudy.
8 ..	Cloudy to fair.
9 ..	Cloudy to fair.
10 Ш	Glow visible through breaks in clouds, 21·04–21·17.
11 Ш	Glow visible through breaks in clouds, 21·06–21·25.
13 ..	Overcast, 20·26–23·50.
14 ..	Cloudy.
16 Ш	Faint aurora, 22·40–23–15.
17 ..	Overcast to cloudy, rain showers.
18 ..	Overcast 19·00–22·32. Rain 20·41–21·42.
19 ..	Moonlight, cloudy.
20 ..	Moonlight, mainly cloudy.
21 ..	Moonlight.
22 ..	Moonlight, fair to cloudy, showers of snow and sleet.
23 ..	Mainly cloudy.
24 ..	Cloudy to fair, snow 20·00–21·04.
25 ..	
26 ..	
27 ..	
28 ..	
29 ..	
30 ..	Cloudy, 20·13–23·04.
	September.
2 ..	Cloudy.
3 ..	Cloudy to overcast.
4 ..	Cloudy to overcast.
5 ..	Mainly cloudy.
6 ..	Cloudy.
8 ..	Cloudy.
9 ..	Mainly cloudy.
10 ..	Cloudy to overcast.
11 ..	Cloudy to fair.
12 Ш	Aurora observed 20·47–21·54.
13 ..	Cloudy.
14 ..	Fair to cloudy.
15 Ш	Very faint aurora, 01·50–02·05.
16 ..	Cloudy.
18 ..	Cloudy, moonlight.
19 ..	Cloudy, moonlight.
20 ..	Moonlight.
21 ..	Moonlight.
22 ..	Fair to cloudy.
23 ..	Cloudy.
24 ..	Cloudy.
26 ..	Cloudy to fair.
27 Ш	Aurora observed 19·20–21·10.
28 ..	Rain showers.
29 ..	Rain showers.
30 ..	Mainly cloudy.
	October.
1 ..	Cloudy to overcast.
2 ..	Cloudy to overcast.
3 ..	Mainly cloudy.
5 ..	Cloudy.
7 Ш	Moderate aurora observed 20·25–23·53.
8 Ш	Moderate aurora observed 20·30–20·42.
9 Ш	Weak aurora observed 21·45–22·05.
10 Ш	Very faint aurora visible through breaks in clouds, 19·55–20·00.
11 ..	Cloudy.
12 Ш	Moderate aurora observed 20·43–21·36.
14 ..	Cloudy to fair, showers, moonlight.
15 ..	Cloudy to overcast, rain.
21 ..	Overcast with rain, 19·00–21·30.
22 ..	Overcast to cloudy, occasional rain.
23 ..	Mainly cloudy, moonlight.
24 Ш	Glow visible between clouds around 22·30.
25 ..	
26 ..	
27 ..	
29 ..	Cloudy, 22·00–24·00.
30 Ш	Moderate aurora observed 19·20–22·34.
31 ..	Cloudy to overcast.
	November.
1 Ш	Aurora observed 19·36–24·30.
2 Ш	Aurora observed 18·40–21·08.
3 Ш	Aurora observed 21·47–22·57.
5 Ш	Very faint glow 19·00–19·15, eclipsed by cloud.
6 Ш	Faint glow, 18·15–18·40, eclipsed by cloud.
8 ..	Mainly cloudy, showers.
9 ..	Mainly cloudy, showers of rain and hail.
10 ..	Mainly cloudy, showers of rain and hail.
11 ..	Overcast to cloudy, rain.
12 ..	Cloudy, hail showers.
13 ..	Moonlight.
14 Ш	Aurora observed 19·05–23·38.
15 Ш	Faint aurora observed 19·15–19·28, eclipsed by cloud.
16 Ш	Aurora observed 19·20–20·29.
17 ..	Moonlight.
18 ..	Moonlight, fair to cloudy.
20 Ш	Aurora mainly obscured by cloud, 17·45–18·10.
23 ..	Cloudy to overcast.
26 Ш	Aurora observed, 19·15–24·00.
27 Ш	Glow, 18·00–23·00.
30 ..	Cloudy.
	December.
1 ..	Cloudy to fair.
2 ..	
3 Ш	Very faint aurora, 18·30–20·00.
4 Ш	Bright aurora observed 19·30–03·20.
5 Ш	Glow visible through breaks in clouds, 21·30–22·00.
6 Ш	Aurora observed 17·37–21·20.
8 Ш	Glow visible through breaks in clouds, 21·30–22·00.
9 ..	Cloudy.
10 ..	Moonlight.
11 ..	Mainly cloudy.
12 ..	Cloudy, occasional rain.
13 ..	Overcast to cloudy.
14 ..	Fair to cloudy.
15 ..	Mainly cloudy.
16 Ш	Aurora observed 18·30–19·24.
17 ..	Cloudy, moonlight.
18 ..	Cloudy, moonlight, showers.
19 ..	Cloudy, moonlight.
22 Ш	Glow visible through breaks in clouds, 19·00–22·00.
23 ..	Cloudy, occasional hail and rain.
26 ..	
27 ..	
28 ..	Cloudy.
29 Ш	Glow visible through breaks in clouds, 19·00–22·00.
30 ..	
31 Ш	Glow, 17·20–24·00.

In the interests of brevity there have been omitted from the table above all dates on which the sky throughout the evening remained completely overcast and on which, therefore, no opportunity arose of determining whether or not aurora occurred. The nights on which aurora was actually seen are indicated by the symbol Ш. The nights on which aurora was not seen, despite at least an occasional interval of more or less clear sky, are indicated by the symbol ... ; in the latter case also, remarks on the weather are added to assist the reader in judging how far the fact of no observation of aurora may be taken as indicating that there was not actual aurora. A full description is available of the auroral phenomena observed.

68. Other Scottish Stations. **1929.**

Date.	Month.
	January.
2	G.C.
3	G.C.
4	B.
5	B.; Oronsay, 18·30 to 19·30; Stornoway; G.C.; Fort Augustus.
9	Dunnet Head, between 18·00 and 19·00.
10	H. glow visible through breaks in clouds, 19·00 to 20·30.
12	H. Faint glow, 21·30 to 23·00.
15	H. glow visible through breaks in clouds, 21·00 to 23·00.
16	H. bright glow visible through breaks in clouds, W. to N.E., 21·30 to 24·00.
28	H. bright glow W. to N.E., 18·45 to 23·00.
30	Eskdalemuir, glow.
	February.
8	B.; H. bright W. to N. up to β Cygnus, 18·50, rays in N.W. 19·00, bright glow W. to N.E., 19·15 to 24·00; Auskerry, 20·00; Oronsay, 20·30; D., faint; G.C. very bright.
9	H. glow visible through breaks in clouds, 19·00 to 21·30, N. to N.E.; G.C.
10	G.C.
17	Stornoway; Fort Augustus, 21·30; Onich; Dunnet Head, between 20·00 and 20·30 to N.W.
18	Nairn.
26	G.C.; Roshven.
27	B.; H. glow visible through breaks in clouds 18·50 to 19·00. Bright band from W. horizon to zenith passing over Venus and Jupiter, fainter rays forming corona round Capella 19·10 to 19·25. Aurora visible through breaks in clouds 19·30 to 23·00. Bright band W.S.W. through S. to E. passing below Alpharet in S.W. and about 20° above moon in E.S.E. Rays flashing upwards very rapidly 23·10. Aurora radiating from a point between λ and μ U. Major, 23·45. Very bright aurora in W.S.W., rays in S. flashing up to zenith 24·00; Covesea between 20·00 and 02·00 of 28th, brilliant display; Tarbetness, a brilliant display until 28th, Holburn Head from 23·00 to 02·00 of 28th; Sound of Mull; Oronsay, 20·00 to 21·20, bright display; G.C., very bright; Fortrose, bright display 19·00 to 20·00; Inverness; Onich; Roshven; Fort Augustus, extraordinary bright aurora of rich pale green colour reaching to height of 60°; Dungavel; Eskdalemuir; Dumfries.
28	B.; H. glow 19·00 to 20·00; Pentland Skerries from 00·30 to 03·15; Noss Head, between midnight of 27th and 03·00 of 28th, unusually brilliant; Dunnet Head, midnight to 03·00 a display all round, shaped like an umbrella; Barnsness 00·15 to 00·45; Isle of May 02·10; Wick; Nairn; Renfrew.
	March.
2	H. faint glow N.E. to N.W., 22·30 to 24·00.
3	H. glow N.E. to W.N.W., 22·00 to 23·00.
6	D. 20·00 to 22·00; Wick 23·30.
7	D. 20·00; G.C.; Arbroath 22·00.
8	H. glow N.E. to W., 22·30 to 00·30 of 9th; Wick 15·00; Dunnet Head midnight to 02·30, brilliant display.
11	North Ronaldshay from 18·00 to 24·00, brilliant display; Ushenish from 19·00 to 05·00 of 12th.
12	H. bright aurora with coloured draperies 19·50 to 20·10, aurora fainter but extending to 12° below Regulus 20·15 to 20·20. Bright aurora with coloured rays over whole sky 20·40 to 01·10; D. brilliant; Kirkwall, aurora all evening, high and shimmering; Wick 20·00; Achnashellach; Braemar; Oban, 20·00; G.C.; A. moderately bright, blue-white 20·00 to 24·00; Nairn; Banff; Tiree; Todhead, from 19·20 to 20·30 in N.; Pentland Skerries 03·00 and 21·00; Stroma, large display; Cantick Head from 00·30 to 04·00 and from 19·30; Hellyar Holm 01·00 to 03·30 in N., and from 22·00 to 05·00 of 13th in N.; Copinsay during evening, and early morning of 13th; Auskerry 02·00 to 03·00 and from 19·30 to 05·00 of 13th. Start Point, seen all night; North Ronaldshay from midnight to 02·00; Eshaness from 20·00 to 24·00. Stretched from E. to W., the northern sky being brightly lit up; Whalsay, from 18·30 to 03·30 of 13th, seen from W. to E., vividly; Dunnet Head 00·30 and from 19·00 to 20·00; Butt of Lewis, between 22·00 and 24·00, brilliant display; Stornoway, 19·20 to 19·30 and onwards to 23·00, all directions; Tiumpanhead 01·00 to 01·30 and from 22·00 to 05·30 on 13th; Ushenish from 19·00 to 24·00; Barrahead 20·30, fine display; Hyskier, between 22·00 and 03·00 of 13th in N.W. sky. Very bright; Oronsay 20·00 to 21·00. Very bright display; Ardnamurchan, a fine display from 04·20 to 05·15; Sound of Mull during the evening.
13	B.; Fort Augustus to height 80°, very light pale green; Pentland Skerries 03·00; Stroma, large display; Cantick Head 20·30 to 21·15.
14	H. bright glow E.N.E. to W., 21·30 to 23·00; Kirkwall low N.W., midnight; D.; A. faint green-white 20·00 to 22·00; G.C.; Barrahead, from 21·30 to 22·00; Oronsay, 20·00 to 20·30; Auskerry 20·00 to 23·00.
15	Wick, 20·00; Inverness, 20·00 to 24·00; Nairn; G.C.; Tiumpanhead from 20·00 to 24·00; Barrahead from 20·00 to 20·30; Ardnamurchan, from 01·00 to 03·30, very bright.
	March (*contd*).
16	Dunnet Head from 00·00 to 03·00 intermittently.

2	Kirkwall, faintly seen about midnight.
14	B.; Braemar; A. faint rose-pink to white, 21·000 to 24·00; Inchkeith, in N.W. from 23·30 to 01·30 of 15th; Auskerry, from 23·00 to 01·30 of 15th.
15	Barnsness, 00·00 to 01·15; Barrahead 00·00 to 01·30.
	September.
3	A. faint glow along horizon N.N.E. to W., 20·30 to 23·00.
5	B.
9	G.C.; A. faint green, 20·00 to 23·00; Inverness.
10	Braemar.
	September (*contd.*).
12	H. glow N.N.E. to W.N.W., 20·45 to 23·00; B.; Fair Isle North, 20·45 to 20·55.
13	Arbroath; Fair Isle North 01·00 to 01·15.
14	H. glow N.N.E. to W.N.W., 22·00 to 23·15; B.; D, slight; Inverness.
22	Arbroath.
27	H. glow visible through breaks in clouds 20·00 to 23·00; B.
30	H. glow visible through breaks in clouds N.N.E. to W., 21·30 to 23·15.
	October.
3	H. glow visible through breaks in clouds N.E. to W.N.W., 21·30 to 23·00.
7	H. bright glow N.E. to W., 21·30 to 22·00. Bright rays up to Capella 22·30 to 23·00; B.; D.; Kirkwall 20·00; Stornoway; Inverness; Arbroath; West Linton; Eskdalemuir; A. moderately bright green-yellow 21·00 to 23·00; Fidra.
8	H. glow above and through breaks in clouds N.E. to W., 19·30 to 19·50; A. faint white-yellow, 20·00 to 24·00; Craibstone; Eskdalemuir; Barnsness, 20·00 to 20·45; Arbroath 21·00, N.
9	H. glow visible through breaks in clouds E. to W., 20·00 to 01·00.
10	A. white 18·00.
12	H. bright glow N.E. to W., 20·00 to 20·30. Rays in N. 21·00 to 23·00. Bright glow N.N.E. to W., 04·00.
14	H. glow N.E. to N., 21·30 to 23·00.
17	D.
23	Kirkwall, N., 19·30.
24	D.; Kirkwall N.W., 23·00.
25	H. glow N.N.E. to W., 20·00 to 24·00; G.C.
26	H. glow along N. horizon 20·00 to 23·00.
27	Kirkwall, N.W., 23·00.
29	H. glow along horizon N.E. to W., 20·00 to 23·15.
30	H. bright glow visible through breaks in clouds N.E. to W., 19·00 to 19·25; Kirkwall, 20·00; D. peculiar aurora at 20·00; Stornoway; A. faint green-white 19·30; Oban; Wick; Eskdalemuir; Inchkeith, 21·00 to 22·15; Dunnet Head, N.E. to W. between 19·00 and 20·00; Tiumpanhead, from 18·00 to 24·00, a vivid display; Oronsay 19·30 to 20·15; Fladda, between 21·00 and 03·00 on 31st; McArthurs Head from 21·10 to 21·45, from N.W. to W.
31	H. bright glow N.E. to W., 20·00 to 23·15; B.
	November.
1	H. glow N.E. to W., 21·00 to 21·10. Aurora with rays to zenith, 21·15 to 21·40; B.; Kirkwall, 22·00; Wick; D. 21·00; Stornoway; Eskdalemuir.

NOTE.—For brevity, stations which figure frequently in the above Table are represented by their initials, viz., D—Deerness, B—Baltasound, A—Aberdeen, G.C.—Gordon Castle, H—Haroldswick, Shetland, where a continuous watch was kept.

INTRODUCTION.

SITE

The Observatory, which was established in 1868, is housed in the top floor of the Cromwell Tower of King's College in Old Aberdeen. The College lies on a plain gradually rising from the sea from which it is distant about 1 mile (1·6 km.). There are no serious irregularities of surface in the vicinity excepting the two river valleys of the Don and the Dee. To the north at a distance of about 1 km. the Don flows eastwards to the sea ; the Dee flows into the sea at a distance of about 3 km. to the south-east of the College. Between the College and the sea is a golf course covered for the most part with grass. Westwards is the High Street of the Old Town and beyond this there is another street. Further west grass pasture extends for about one kilometre. Southward are some open spaces beyond which the modern town is reached. The enclosure in which the Stevenson screen, the Beckley and check rain-gauges and the grass minimum thermometer are exposed, has had its position changed since 1928 on account of the extension of the College buildings. Its position was, in previous years, about 50 metres to the north-east of the Observatory, but from the 1st June and onwards, the site has been a new one, also to the north-east of the Observatory, but at a distance of approximately 180 metres. The height of this " station " above M.S.L. is 11·4 metres. The " North-wall " screen in which the recording thermometers are exposed is erected on the wall outside the north window of the uppermost storey of the Observatory. The nature of the soil and sub-soil is loam and sand.

Plans showing the position of the Observatory relative to the City of Aberdeen, and the general arrangement of the College Buildings, and also photographs, are given in the volume for 1928. The enclosure shown is that on the new site. A view of the old site will be found in the Introduction to the Observatories' Year Book, 1923.

Change of value adopted for height of Station above Mean Sea Level.—There have been one or two changes lately in the values adopted for the height of the Station above Mean Sea Level. Prior to 1st January, 1925, the value for the station level was 14·0 m., and that for the height of the barometer cistern was 26·8 m. As from

* These values differ slightly from those given in former years. See note above.

1st January, 1925, however, following a careful redetermination of these heights, the values were altered to 13·4 m. for the station level, and 26·0 for the height of the barometer cistern. The change of site of the rain-gauge enclosure, referred to above, has further altered the value for the station level to 11·4 m. as from 1st June, 1928, but the height of the barometer cistern remains as before, viz. 26·0 m.

METEOROLOGY.

The elements dealt with in the following tables are :—Atmospheric pressure, air temperature, humidity, rainfall, sunshine, wind speed and direction, earth temperature and minimum temperature on the grass, together with a diary of cloud and weather.

The instruments from which values of the above elements have been obtained and the methods of tabulating the records are described in the General Introduction to this volume. The following additional information refers especially to Aberdeen.

Pressure and Temperature.—The photo-barograph, standard Fortin barometer and thermograph are housed in the Observatory room. The pressure scale value of the photo-barogram is 1 mb.= 1·18 mm. on the paper, when the paper is at normal atmospheric humidity. In similar circumstances the time scale is 1 hour = 9·3 mm. The records of the photo-barograph are standardized by means of control readings taken from the standard barometer. Up to the end of 1928 this instrument was Fortin Standard Barometer M.O. 273, but from the 1st January, 1929, it has been replaced by Fortin Standard Barometer M.O. 1149. The N.P.L. certificate of this latter barometer shows a standard temperature varying from 286° A at 1,050 mb. to 287° A at 910 mb. ; corresponding corrections have been applied to the control readings.

The recording thermometers are placed in the North-wall screen already referred to. The scale value of the wet bulb thermograph record is 1° absolute = 3·20 millimetres on the paper ; for the dry bulb thermograph the scale value varies slightly with the temperature, but is approximately 1° absolute = 3·4 millimetres. The time scale is 1 hour = 9·23 millimetres. Reading of the photothermograms is done by means of glass measuring scales, the records being standardized by control readings from Standard Thermometers M.O. 1698 (dry bulb) and M.O. 1697 (wet bulb). These thermometers have corrections, varying at different parts of the scale of between −0·1° A and +0·2° A ; these corrections have been applied to the control readings. The heights of the barometer cisterns and of the bulbs of the thermometers are given at the top of the appropriate tables.

It may be here emphasized that the bulbs of the thermometers in the North-wall screen are at the considerable height of 12·5 metres above the ground, and that readings from these thermometers are exclusively used for this publication (except as noted below under *Humidity*) and for the corresponding summaries printed in the *Monthly Weather Report.**

Rainfall.—The recording instrument in use is Beckley rain-gauge No. 2 with an area of 101·1 square inches (653 cm².). The procedure adopted in tabulating the records is similar to that described in the General Introduction and calls for no comment. Control was by check gauge M.O. 266 during the year 1929.

Humidity.—On those occasions when the temperature of the wet bulb has been 273° A or under, the relative humidity has been obtained from the records of a hair hygrograph. This instrument is accommodated inside the new large Stevenson screen at the new site. The hygrograph is now 13·2 metres below the level of the thermograph bulbs in the North-wall screen, and in using its records an appropriate adjustment is made.

* The temperatures for Aberdeen published in the *Daily Weather Report*, and summaries from them given in the *Weekly Weather Report* are from different thermometers, viz., those in the Stevenson Screen with their bulbs only 1·3 metres above the ground.

Sunshine.—The sunshine recorder (Campbell-Stokes type) is exposed on the small circular tower on the Observatory roof on which the Robinson Cup Anemograph is erected. It is rigidly held by lead flaps soldered to the lead roof. The actual diameter of the sunshine sphere is 4·02 inches, and the focal length 2·97 inches, these figures being slightly in excess of the standard values (diameter 4·00 $\pm$·05 inches, focal length 2·95 $\pm$·01 inches). The exposure is excellent ; the only obstruction is a flagpole to the east, of angular diameter about 1°, which may obstruct 0·1 hr. record about 7h between April and September. This loss has been allowed for, whenever practicable, in tabulating the records. In computing the percentage duration of sunshine the actual possible values for each day of the year 1929 have been employed, a procedure similar to that adopted from 1926 onwards.

Wind-Speed and Direction.—As stated in the General Introduction, the values for 1929 are tabulated from the records obtained by the Dines Pressure-tube Anemograph. This instrument is one of the "standard mounting" type, and is situated in a field about $\frac{1}{2}$ km. east of the Observatory. The exposure is a more open one than is that of the Cup Anemograph, the records of which were tabulated previous to 1926. The effect of this exposure upon the recorded values is given in the Table in the General Introduction.

In a few instances where the records of the Pressure-tube instrument have been defective, the required values have been obtained from the records of the Cup instrument, a suitable adjustment of such values having been made in accordance with the data given in the above-mentioned table. Values thus obtained are entered in italics.

Temperature in the Ground.—This is recorded by a thermometer (unnumbered), which is kept at a depth of 124 cm. (four feet). At Aberdeen the thermometer is carried in a slot near the end of a long bar of wood, about three inches (7·5 cm.) square in section. This bar fits closely into a wooden sleeve, sunk vertically into the earth, so that the bulb of the thermometer is at the required depth. The thermometer itself is enclosed in a glass tube, and its bulb is embedded in paraffin wax so as to render the thermometer insensible to sudden changes of temperature. This allows of its being drawn to the surface and read before the temperature of the bulb has time to change appreciably. As underground temperature changes very slowly, the loss of sensitiveness, resulting from the coating of wax, does not lead to inaccuracies in the determination of the temperature of the earth. The thermometer is read at 9h each morning. The thermometer has a correction of $-0{\cdot}2°$ A ; this correction is applied to all readings.

Minimum Temperature on the Grass.—The grass minimum thermometer is exposed in the enclosure on two wooden pegs about 4 cm. above grass. It is set at 18h and read at 7h, the reading being entered to the day of observation. There is no correction to grass minimum thermometer M.O. 17866.

Cloud.—In connection with the observations of cloud-forms it might be well to indicate the practice adopted at Aberdeen in dealing with the types Nimbus and Strato-cumulus, in view of the fact that there exists among meteorologists some divergence of opinion upon these types, and also because suggestions have been made for a prospective modification in the definitions of the International Classification.

In the case of Nimbus it is the custom at Aberdeen to enter " Nb " on all occasions when the cloud layer from which rain is falling is obviously dense and has developed from A-St, even when no Fr-Nb is visible below it. This is done because it is not always certain to the observer whether the cloud-layer is actually uniform low A-St developed

as far as rain, or whether a slight mist-film exists below the ragged Fr-Nb., obscuring the latter from view, and thus giving it the appearance of a uniform featureless sheet. (It is probable that in future a suggestion will be made to extend the definition of A-St in the International Classification to include the dense rain-giving layer which develops from the normal A-St.)

On occasions when the low anticyclonic stratus degrades into drizzle or light rain, it is customary at Aberdeen to enter Nb-St (Nimbo-stratus). The entry " St " is reserved for the type of cloud found generally in dry anticyclonic weather.

The entry St-Cu includes only the cloud-forms as defined under that heading in the International Classification, though some of the entries might equally well have been termed A-Cu. It does not, however, include the bases of closed-up cumulus clouds, nor groups of cumulus arranged in lines.

Visibility.—In the subjoined table there is given a list of the objects used for the determination of the degree of visibility, together with their distances and bearings from the observation-point, which may be taken as the roof of the Observatory tower, the N.E. corner thereof being used for the nearer objects.

The range of visibility from the Observatory is somewhat limited by the high ground surrounding the city. From S.E. through S. to N. the distance of the visible horizon is between 2 and 4 miles (4 to 7 km.), but in the N.W. a higher hill, at a distance of 5 miles (8·5 km.), rises above the nearer ridges. To the N.N.E. however there is a clear view of the coast-line as far as Cruden Scaurs, where the coast consists of cliffs over 100 feet high, and is nearly 19 miles (30 km.) distant. From N.N.E. to S.E. there is only the sea-line as horizon, which from the height of the Observatory tower is about 10 miles (16 km.) distant.

Definite objects exist at standard distances from A to H, but from I to M there are no definite objects, though there are adequate identification marks for K and L. Owing, however, to these marks being on the sea-coast, and to the generally clearer visibility to the seaward side of the Observatory, it has been deemed advisable to employ small letter entries for all visibility distances that are not definitely landward estimates. The distances I and J are based upon estimates between other available distances. During darkness the estimates depend upon personal judgment, and upon the degree of obscuration, and alteration in the colour, of the surrounding lights of the town.

VISIBILITY OBJECTS AT ABERDEEN.

Earth Thermometer	—
Grass Minimum Thermometer	M.O. 17866

* Replaced by M.O. 154/27 on 14th May 1929.

Review of Meteorological Results

Pressure.—The mean pressure over the whole year was only very slightly in excess of the normal value, but its behaviour throughout the months was noteworthy, there being a large excess from January to March, fairly normal values from April to September, and a large deficit from October to December. The maximum excess was somewhat over 14 mb. in January; the greatest deficit was almost 13 mb. in December. The months of greatest pressure disturbance were October, November and December with average daily ranges of 12·0 mb., 11·2 mb. and 13·5 mb. respectively. The monthly range of pressure reached the high value of 77 mb. in December, while the extreme range of pressure during the year was 85 mb.

The mean diurnal inequalities for the months, seasons and year have been analysed harmonically, with the results set out in the accompanying Table. The unit employed for the months is, as before, ·01 mb., that for the seasons and the year is ·001 mb., and the phase-angles are reduced to Local Mean Time. The average values of the various coefficients for the period 1871-1926, computed by Dr. A. Crichton Mitchell*, are given for comparison.

The inequality is supposed to be given by the expression—

$$c_1 \sin(15t^\circ + \alpha_1) + c_2 \sin(30t^\circ + \alpha_2) + \ldots\ldots$$

t being the time in hours since midnight.

Harmonic Components of the Diurnal Inequality of Atmospheric Pressure—Aberdeen, Longitude 2° 6′ W.

Values of c_n, α_n, in the series $\Sigma c_n \sin(15nt^\circ + \alpha_n)$, t being Local Mean Time reckoned in hours from midnight.

* Diurnal Variation of Pressure and Temperature at Aberdeen, 1871-1926, by A. Crichton Mitchell, D.Sc., Q.J.R. Met. Soc., 1929, p. 197.

This year the values of the 24-hour term-amplitude, c_1 vary very greatly from month to month, reaching the unusually high value of ·78 mb. in December, while the phase-angles, α_1, exhibit the usual irregularity.

In the case of the 12-hour term, the values of c_2 show spring and autumn maxima, and summer and winter minima more sharply marked than they are on the average. The phase-angles, α_2 do not depart widely from their mean value, except in the month of December which shows a value about 50° below the normal. The corresponding amplitude, c_2, for that month has, however, only half its average value, being only ·12 mb. December was remarkable for its very high value of c_1 (·78 mb.), its disturbed and very low pressure, and great pressure-range.

The 8-hour and 6-hour terms follow their usual courses fairly well. The seasonal variations in amplitude of the former term, though definite, are not so strongly developed as in 1928, but the reversal of phase from winter to summer is very regular. In the case of the 6-hour term the value of c_4 at the winter maximum is considerably above the average; this was likewise the case in 1928.

The variation in the individual monthly values of c_2, c_3 and c_4 is somewhat less than in the preceding year, but is greater in the case of c_1.

Temperature.—The outstanding feature of the year 1929 was the coldness of January and February, which months were 1·2° A and 1·6° A respectively below their normal values. This was followed by a great upward surge of temperature which resulted in March having an excess of 1·6° A. Temperature fell again in April when there was a deficit of 1·1° A; April being in fact actually colder than March. After this irregularity the monthly values agreed fairly well with the normal, except in September and December, both of which months had excesses of 1·4° A.

Rainfall.—1929 was a year of excess precipitation; the eight years since 1922 have now yielded a total excess of 520 mm., of which amount 1929 has contributed 35 mm. But the year was one of great contrasts in rainfall; March with only 5 mm.—a deficiency of 56 mm.—was almost a record month for dryness; and September again had a deficiency of 23 mm. Against these there are to be mentioned an excess of 24 mm. in July, and a very large excess of 85 mm. in December.

Viewed in the light of its general distribution the rainfall of 1929 showed considerable relation to the pressure; the unusually high pressure of January, February and March coincided with a deficiency of 72 mm. of rain, while the very low pressure of October, November, and December was accompanied by an excess of 104 mm. In December the incidence of rainfall during the night was well marked.

Relative Humidity.—This was higher than normal in January and February during the very cloudy weather of that period, and lower during the period from June to October. Some slight general relation to the distribution of sunshine is shown, but none to the incidence of rainfall. Particularly worthy of note are the cases of March, which, with only slight precipitation, had a relative humidity slightly above normal, and December, which, with more than double its usual rainfall, had a relative humidity well below the average.

Sunshine.—The total amount of sunshine during the year was slightly above the average. There was a large deficiency during the anticyclonic weather of January and February—the latter of these two months received only 14 per cent. of the possible, i.e. only half the usual amount—but March showed an excess of 8 per cent. Thereafter there was no great departure from the normal monthly values until September, which, with an excess of 9 per cent., showed the highest monthly percentage of possible sunshine. From September onwards to the end of the year there was a continued excess of sunshine amounting to an average of about 8 per cent. over the whole period. This is the more remarkable inasmuch as the period from October to December was very much wetter than usual.

Wind.—The average velocity of the wind for the year was 4·4 m.p.s.; this is less than the value for 1928, nevertheless there is a considerably greater range between the individual monthly values in the present year. The windiest months were December (6·4 m.p.s.) and February (6·0 m.p.s.), the most quiet was March (3·3 m.p.s.). Despite the general storminess of December, only one gale was recorded,—that of December 25th, during which the highest gust of the year occurred; it reached 31·1 m.p.s. (70 m.p.h.) The prevailing winds were from the southerly and westerly sectors.

Aurora.—The number of occasions upon which aurora was observed was 17, all but 2 of which occurred in the latter half of the year. There were thus 8 fewer occasions than in the previous year. November was again the month of maximum frequency. The dates of occurrence will be found in the General Auroral Table.

General.—The year as a whole was one of marked contrasts. A cold, dry, dull and windy January and February were followed by an unusually quiet, warm, sunny, and abnormally dry March. April was cool but otherwise fairly normal. The period from May to August was likewise fairly normal except that July was wetter than usual. September was dry, warm and sunny. October, November and December were all much brighter than usual, October and November having rather more than the normal rainfall, but average temperature; while December was exceptionally wet, stormy and warmer than usual.

Readings in millibars at exact hours, Greenwich Mean Time.

Station Level

NOTE.—When pressure exceeds 1000 mb. the leading figure 1 is not printed, *i.e.*, 1005·6 mb. is written 005·6. This rule does not, however, apply to monthly means.

Readings in millibars at exact hours, Greenwich Mean Time.

71. Aberdeen : H_b (height of barometer cistern above M.S.L.) = 26·0 metres. **March, 1929.**

114. Aberdeen. NOTES ON RAINFALL. 1929.

Notable Falls of the Year.—The most notable fall during the year was one of 51 mm. on the 31st July. It is referred to below. There was no instance of a high rate of rainfall, the highest being 5 mm. in 20 minutes on 29th July.

Dry Periods.—(Periods of 7 days or over with no rainfall or with trifling falls.)

Mar. 5—20. 16 days with no rainfall. From 28th February to 20th March, a period of 21 days, only 0.6 mm. fell. The whole month of March yielded only 5 mm. of rainfall.

July 11—21. 11 days with no rainfall, followed by another period of 5 days from July 23—27, also with no rainfall.

Sept. 10—17. 8 days with 0.2 mm. of precipitation.

Wet Periods.—(With notes of the heavier rates of fall.)

July 29—31. Following a dry spell, 72 mm. fell on these three days, 51 mm. of which fell in less than 12 hours, and 25 mm. in 4 hours, on the 31st.

Nov. 19. 22 mm. fell in a little over 9 hours.

Dec. 20—25. During this period 118 mm. of rain were recorded, of which 25 mm. fell in a little over 4 hours on the 21st. December was a particularly wet month throughout, 167 mm. in all were recorded.

Amounts in millimetres, for periods of sixty minutes, between the exact hours, Greenwich Mean Time.

115. Aberdeen : H_r (height of receiving surface above M.S.L.) = H (Height of station above M.S.L.) + h_r (height of receiving surface above ground) = 11·4 metres + 0·6 metres. **January, 1929.**

Hour. G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 8 metres + 13 metres.

January, 1929.

Hour. G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 8 metres + 13 metres.

March, 1929.

Hour. G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 8 metres + 13 metres.

July, 1929.

Hour.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 8 metres + 13 metres.

September, 1929.

Averages for periods of sixty minutes centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 8 metres + 13 metres.

November, 1929.

INTRODUCTION.

HISTORICAL.

Early in the twentieth century the increasing artificial magnetic disturbance at Kew Observatory, Richmond, due to the westward extension of the electric tramway system from London, made desirable the establishment of a magnetic observatory in a locality unlikely to be affected, at least for a large number of years, by electric power or traction systems. A committee of the Royal Society of London selected a site in the parish of Eskdalemuir, Dumfries-shire, for the new observatory. The nearest towns or industrial centres are Langholm and Lockerbie, distant approximately 16 and 18 miles (26 and 29 km.) by road, and there is no point of railroad within 9 miles (14 km.) of the Observatory. Installation of the instrumental apparatus commenced in the summer of 1908, the Observatory at that time forming a part of the then recently established National Physical Laboratory.

Although the Observatory was established primarily in the interests of the study of terrestrial magnetism the field of geophysical work undertaken has been considerably wider and has included, almost from the beginning, meteorology, atmospheric electricity (mainly atmospheric potential gradient), and seismology. In the earlier years Milne, Wiechert, Omori, and Galitzin seismographs were in operation at Eskdalemuir, but seismological observations ceased in October, 1925, when the three-component installation of Galitzin seismographs was transferred to Kew Observatory. In 1910, when the majority of the various initial difficulties had been overcome, Eskdalemuir passed from the control of the National Physical Laboratory to that of the Meteorological Office. In consequence of this change the meteorological work assumed increased importance, and from the beginning of 1914 the Observatory has served as a telegraphic reporting station of the Meteorological Office.

Summaries of the results of observations made in 1909-10 were published in the Report of the Observatory Department of the National Physical Laboratory, 1909-10. The results for subsequent years are included in the publications mentioned in the Preface to the present volume.

SITE.

Eskdalemuir Observatory, some $3\frac{1}{2}$ miles ($5\frac{1}{2}$ kilometres) north-north-west of Eskdalemuir Parish Church in the county of Dumfries-shire, is situated on a rising shoulder of moorland which is bounded on the east by the road which leads north to Ettrick and Selkirk, on the west by the small Davington Burn, and at the southern extremity by the small hamlet of Davington.

The hillside in the immediate vicinity of the Observatory slopes generally from the north-west to south-east. The mean height above sea level of the Observatory site is about 800 feet (244 metres). Cassock Hill, slightly more than a mile distant to the north-west, is 1,205 feet (367 metres), while the bench mark at Davington School, ¼ mile (0·4 km.) to south-east, is 699 feet (213 metres) above M.S.L. To the east the ground slopes fairly rapidly to the valley bottom, the level of the Ettrick road at a point about ¼ mile (0·4 km.) east of the underground magnet house being 682 feet (208 metres). The River White Esk is rather less than ½ mile (0·8 km.) to the east. Immediately beyond the river, and almost due east of the Observatory, Dumfedling Hill rises to a height of nearly 1,200 feet (366 metres) above M.S.L. Some 4 or 5 miles (8 km.) to the north is a high ridge, following approximately the boundary between Dumfries-shire and Selkirkshire, the highest point of which is Ettrick Pen (north-north-west) 2,200 feet (670 metres) above M.S.L. Rather more than half a mile (0·8 km.) to the west, and beyond Davington Burn, the ground rises to 1,040 feet (317 m.), and reaches nearly 1,200 feet (366 m.) half a mile (0·8 km.) further on. To the south and south-south-east the Observatory commands a view of the White Esk Valley as far as Hart Manor, 4 miles (6½ km.) distant, and beyond that the upper slope of Cauldkine Hill, about 10 miles (16 km.) distant, is visible. The surrounding country is bare and wild and there are but few trees to relieve the monotony of the grass-covered hills and moorland.

Within the Observatory grounds the soil is peaty and in many places is more or less boggy at all seasons. Some two feet, or less, below the surface a clay-like substance containing soft rock is encountered. The local geological formation is described as "rock of the Tarannon Llandovery series traversed by igneous dykes."

Photographs, site plan, and a brief description of the Observatory will be found in the Introduction to the Observatories' Year Book, 1928.

METEOROLOGY.

The elements dealt with in the following tables are:—Atmospheric pressure, air temperature, humidity, rainfall, sunshine, solar radiation, wind speed and direction, earth temperature and minimum temperature on the grass. There is also a diary of cloud and weather.

Notes on Instruments.

Brief descriptions of the recording instruments and of the methods of tabulating the records, with notes on the information contained in the Tables, are given in the General Introduction to the Tables. The following particulars, which refer specially to Eskdalemuir, are to be regarded as amplifying the information contained therein. References to full accounts of other instruments used at Eskdalemuir appear below.

From 1st January, 1929, the former standard Kew pattern mercury barometer was superseded by a Fortin baormeter, by C. F. Casella & Co., London. From 1st January to 20th August the instrument was situated in a ground-floor room having a small daily range in temperature, the cistern of the instrument being at the same level as that of the old standard. From 20th August to 31st December it was in the ground-floor laboratory on the same level as before. When the Fortin barometer was first set up it read 0·4 mb. higher than the Kew pattern barometer on the average, but by improving the illumination and method of observation, the average difference was reduced to 0·1 mb., which is the error of observation. At present the average difference is 0·05 mb. The vernier setting edge over the mercury column of the Fortin barometer is not quite horizontal but is inclined at an angle of

7 minutes of arc to the horizontal. The maximum error introduced by variations in the point of apparent contact between the mercury and the edge is less than 0·01 mb. The smallest division on the vernier scale is 0·05 mb.

The photographic mercurial barograph is situated in the east room of the underground magnet house. The daily range of temperature to which the instrument is subject is normally less than 0·05°C., the annual range being about 4°C. The scale value of the records is 1 millimetre on the paper = 0·85 millibar, and the time scale is 9·1 millimetres on the paper = 1 hour.

As in former years, records of pressure were also obtained from (*a*) a Dines float barograph[1], and (*b*) a Richard barograph, pen recording, the records of which are changed weekly.

Temperature.—The photographic thermograph and the standard mercurial thermometers, dry bulb and wet bulb, are situated in a wooden hut, provided with louvred sides and double roof, which is some 200 feet (60 m.) north-north-east of the main building. The installation is similar to that described on p. 10, except that a special enclosure is provided inside the hut to accommodate the optical and photographic arrangements. The Standard Wet Bulb Thermometer was accidentally broken on 30th October. An auxiliary thermometer was fitted immediately after its corrections had been determined at the Observatory by comparison with a standard thermometer.

The scale values of the thermograph records are 1a. = 3·064 mm. and 2·438 mm. on the paper for the dry and wet bulb records respectively, while the time scale is 1 hour = 9·250 mm.

Auxiliary records of temperature are obtained from one or more instruments of the bimetallic type described in the *Meteorological Observers' Handbook*. These instruments are situated in the hut which contains the photographic thermograph.

Humidity.—In addition to the dry and wet bulb thermograph described above there is a Richard hair hygrograph which is situated in the louvred hut.

As is stated in the General Introduction, the records from this instrument are utilised when the wet bulb reading does not exceed 273a. On the records obtained in 1929 a change of 10 per cent. in relative humidity is represented by about 0·8 centimetre, the time scale being 1 hour = 3 millimetres.

Rainfall.—The recording instrument is a Beckley self-registering rain-gauge, which is described on page 11. The time scale of the record is 1 hour = 9·24 millimetres on the paper and the rain scale has a magnification of 3·35. The instrument has been in use at Eskdalemuir since 1908 and was originally installed at Fort William in July, 1890.

The conical part of the gauge funnel is surrounded by a cylindrical copper casing lined with asbestos on the inner side and of diameter equal to that of the funnel, viz. 11·27 inches (28·6 cm.). Within the enclosure so formed is a gas jet, and a flame of suitable dimensions is maintained, as circumstances dictate, to melt snow which may be collected.

The gauge is surrounded by a circular turf wall or dyke, the top of which is on a level with the rim of the gauge; the external and internal diameters of the dyke being 11·5 feet (3·5 m.) and 7 feet (2 m.) respectively.

[1] Q.J.R. Meteor. Soc., Vol. LV, pp. 37-53, 1929.

A standard 8 inch (20·3 cm.) rain-gauge is situated some 24·5 feet (7·5 m.) to the east of the Beckley gauge and is surrounded by a turf dyke of similar dimensions. Readings of amounts of rain received in the 8 inch gauge are made at 7h and 18h G.M.T. It is customary to adjust the indications of the recording gauge to agree with the readings of the standard check gauge. A new rain-gauge measuring glass was introduced on August 30—when the old measure was broken.

Until May 14 and again after November 8, 1928 auxiliary autographic records of precipitation were obtained by means of a Hellmann-Fuess snow-gauge. In the former period the exposure of the instrument was as described on p. 142 of *The Observatories' Year Book*, 1927. Since then the gauge has been in a somewhat deeper pit 8 feet (2·4 m.) almost due north of the 8 inch standard gauge, the pit being surrounded by a low wall of earth and turf—the top of the wall being approximately level with the rim of the gauge. The records so obtained are used only in the event of failure or uncertainty of the Beckley autographic record.

Sunshine.—The record of sunshine is obtained from a Campbell-Stokes recorder described on p. 11.

The recorder is fixed on a stone pillar and has a reasonably free exposure, the chief obstacles being hills to east and west. The elevation of hills between 70° and 110° east of south varies from 2·5° to 5°, while between 50° and 135° west of south the high ground varies in elevation from 3° to 4·4°, being generally about 3·5°. As sunshine can be recorded when the sun is 3° above the horizon only in the most favourable circumstances, it appears that the loss of record occasioned by the neighbouring high ground is of relatively small extent and is confined mainly to a possible defect of record at the beginning of the day during a few weeks centred about the equinoxes.

Solar Radiation.—Measurements of the intensity of radiation received from the sun by a surface which is normal to the line drawn from the instrument to the sun are effected by means of an Ångström compensating pyrheliometer.[1] The intensity of radiation is expressed in milliwatts per square centimetre (1mw. per sq. cm. = 0·01435 gramme calorie per sq. cm. per minute). In addition, the value is given of the function (p/p_0) sec Z, in which p is the barometric pressure at the observatory in millibars at the time of the observation, p_0 is 1000 millibars, and Z is the zenith distance of the sun. This affords a measure of the mass of atmosphere which the solar radiation has had to penetrate before reaching the earth. Entries in the column headed "Sky" are intended to show the presence or absence of haze, mist or cloud in the direct path of the solar radiation recorded.

Wind.—A Dines tube anemograph, furnished with direction recorder, is situated in the main building. The vane-head is 15 metres above a tangent plane to the slope of the hillside and approximately 7 metres above the general level of the roof of the building.

The anemograph vane in use throughout 1929 is that which was introduced in August, 1925. It differs from that formerly in use in that the greatest dimension of the fin is vertical instead of horizontal, and that the cross-section of the fin is of aerofoil shape. A twin-lever direction recorder has been in use since June, 1925.

[1] For description see *The Observer's Handbook*, 1921, Ed., Meteorological Office, London; *Astrophysical Journal*, Vol. IX, 1899; *Actes de la société royale des Sciences d'Upsal*, 1893; also *Geophysical Memoirs*, No. 21 (1923), Meteorological Office, London. The pyrheliometer was under repair until June, 1929.

In this instrument a pen is carried by each of two pivoted arms, upper and lower. A projection from each arm engages with a flange of a dual helical device cut in a short cylinder (of vertical axis) which rotates with the vane, being connected thereto by a vertical "rod" consisting of steel tubing 1·5 cm. external diameter.

On August 18 the top coupling on the direction rod became loose. It was impossible to remove the reducing socket on the mast without damaging it, and pending the receipt of a new one on September 13, velocity only was recorded between the two dates mentioned. A new clock drum was fitted on November 29. During alteration to the buildings the anemometer recorder was enclosed in a dust-proof cupboard, but frequent loss of record occurred through grit and moisture collecting on the rod.

Apart from the surrounding hills, the exposure of the vane-head is tolerably free in all directions save to the west where at a distance of some 130 feet (40 m.) is a rather large building, of which the height is somewhat greater than that of the main building. With winds from nearly due west the direction records show markedly greater turbulence than with other winds.

Earth Temperature.—Readings have been made at 9h G.M.T. of the earth temperature at nominal depths of one foot and four feet below the surface of the grass lawn a few yards south of the thermometer hut. The thermometers and the method of exposure are of the standard type described in the *Meteorological Observers' Handbook.* The depths of the thermometer bulbs below the grass-covered surface of the ground are 30 and 123 cm. Graduation is on the Fahrenheit scale.

Minimum Temperature on the Grass.—The thermometer used for readings of grass minimum temperature is of the spirit type with index; and when exposed, between 18h and 7h G.M.T., is supported at a height of one or two inches (4 cm.) above close-cropped grass a few metres from the louvred thermometer hut.

Visibility.—The descriptions of the selected visibility objects, together with the distances and bearings from the point of observation, are given in the subjoined table. Auxiliary objects and guide criteria are given in brackets. Certain of the nearer objects may be identified by reference to the photographs and site plan. Unless otherwise stated, the distances and bearings are with reference to certain of the windows on the upper floor of the main building.

The situation of the Observatory and the nature of the immediate surroundings allow of only a very limited choice of objects. The objects A to D are situated mainly to the north, while the more distant objects are towards south to south-east, *i.e.*, down valley. Four miles or so to the north of the Observatory the hills rise in places to rather more than 2,000 feet above sea level and at times visibility in this direction is distinctly less than towards south. On other occasions the hills to the north are visible, but nearer objects down the valley are invisible owing to valley mist. With the exception of the cottage at Finglandshiel, and Cauldkine Hill, the objects more distant than D are below the level of the Observatory. There are no objects at distances which approximate sufficiently closely to the standard distances for objects H, J, and K. When it is estimated that the range of visibility is such that objects at these standard distances would be visible the corresponding small letter entries are made in the Diary of Cloud and Weather. The estimates of visibility in the dark depend largely on the judgment of the observer. There are no lights other than those in the Observatory buildings and in two cottages within a radius of one mile.

Corrections to Instruments in Use in 1929.

The corrections to the instruments in use during 1929 are given below. Except in the case of the standard wet bulb thermometer used from 30th October, the corrections are those given in the certificate of examination issued by the National Physical Laboratory. The corrections here given have been applied. The date on which each of the instruments mentioned was brought into use is given for purposes of reference.

Note on the Reduction of Barometer Readings.

The Fortin barometer, M.O. 1716/27 by Casella, London, has been used as the standard since 1st January, 1929. Before this date a Kew pattern mercury barometer M.O. 1320 by J. Hicks, London, was the standard instrument from 16th December, 1913.

1. *Reduction to Pressure at Station Level.*—The corrections for index error (including those for capacity and capillarity) as given in the N.P.L. certificate dated June 28, 1928, are reproduced above. The corrections for temperature are those given in the *International Meteorological Tables* as appropriate to a Fortin barometer.

The corrections for the variation of gravity as obtained from the expression

$g = 980{\cdot}617\ (1 - {\cdot}00259 \cos 2\lambda)\ (1 - 5z/4E)$

where λ = latitude
z = height of the station.
E = earth's radius

2. *Reduction to Mean Sea Level.*—The correction to reduce pressure at station level to pressure at sea level is calculated according to the usage of the *International Meteorological Tables* with certain minor modifications which are set out in *The Observatories' Year Book*, 1928. In the same volume is given a copy of the Table actually in use.

Notes on the Meteorological Summaries.

The number of years for which meteorological results are available is insufficient as yet to yield a completely representative set of normal values. Although certain meteorological data are available for 1909 and 1910 it is only since 1911 that the reductions have been made in accordance with an approximately uniform plan. In the following notes the normal or average values referred to are for the period 1911 to 1926, unless otherwise stated.

Pressure.—As was the case generally in the British Isles the mean pressure for the year was above normal, the increase at Eskdalemuir being 1·5 mb. Only in October, November and December were the monthly means below normal, and then they were conspicuously below normal. The extreme instantaneous values recorded were 1013·7 mb. on January 12, and 931·1 mb. on December 7. The greatest and least mean daily values are 1013·0 mb. on January 12 and 943·3 mb. on December 5. The largest value of the range during a calendar day is 30·1 mb. on December 7. The mean value of the absolute daily range of pressure varies between 13·4 mb. in December, and 4·5 mb. in July. The annual mean value of the daily range is a little above normal.

Pressure (*Diurnal Variation*).—In the mean diurnal inequality for each month there are two maxima, in the late forenoon and usually an hour or two before midnight, and two minima, in the early forenoon and afternoon. In all months, excepting January, March and November, of 1929, the night maximum is the larger and except for January, February and November this is true of the representative inequalities for the years 1911–20. The principal minimum in the latter inequalities is in the afternoon except in February, March, August and November, but in 1929 the principal minimum falls in the early forenoon in January, June, August, September, October, November and December. Compared with the mean diurnal inequality for 1911–20[1] the values of the mean inequality for the year 1929 are algebraically less from 2h to 13h and greater from 14h to 24h. In other words, relatively speaking, in 1929 the early morning trough and the night crest are enhanced, while the afternoon trough and the forenoon crest are diminished.

The results of the harmonic analysis of the monthly and seasonal mean diurnal inequalities for 1929 are given in the accompanying table. For purposes of comparison the corresponding data [1] derived from the mean inequalities for the period 1911–20 are also given. In computing the Fourier co-efficients for 1929 the unit employed was ·001 mb. Although for 1929, as for recent years, the phase angles are given to the nearest 1°, this course is scarcely justified, at least for the third and fourth components, by the character of the data from which the harmonic co-efficients for the months and seasons of a single year are computed. The phase angles α_1 etc. given in the table below refer to Local Mean Time, whereas in the corresponding tables for 1922 and 1923 the phase angles refer to Greenwich Mean Time.

As is usually the case the amplitude and phase of the 24-hour term fluctuate irregularly from month to month. The ratio of the mean of the twelve monthly values of c_1 to the value of c_1 for the year as a whole considerably exceeds unity. c_1 is noticeably high for September and for December, low for November. The values of c_2 for the year, equinox, winter and summer, are nearly equal to the corresponding normals. The variation in the 8-hour term from month to month is fairly normal, the amplitude being largest in winter months and least at the time of equinoctial phase transition. The values of c_3 for the year, winter, equinox and summer are slightly above normal. For the 6-hour term also, the amplitude for the year, winter and summer, is above normal.

Note.—*Winter* comprises the four months January, February, November, December.
Equinox the months March, April, September, October.
Summer the months May to August.

Temperature.—The mean temperature, 279·57a. (43°·9 F.) for the year 1929 is slightly less than the normal value. Monthly mean values depart from the corresponding normals by amounts varying between +1·5a. (2°·7 F.) in September to −3·4a. (6°·1 F.) in February. February was the coldest month of the name since records commenced at Eskdalemuir, having been slightly colder even than February 1917. The extreme temperatures recorded during the year were 298·6a. (78°·1 F.) on July 15 and 259·9 (8°·4F.) on February 28. February 13 with mean daily temperature, of 264·6a. (16°·9F.) was the coldest day of the year. According to mean daily temperature July 16 with 291·3a. (64°·9F.) was the hottest day of the year. The values of the absolute range of temperature within a calendar month vary between 27·8a. (50°·0F.) in March and 16·3a. (29°·3F.), in December. Values not in excess of 273·0a. (32°·0F.) are :—mean daily temperature on 36 days (16 in January, 13 in February), minimum temperature on 121 days (25 in January, 26 in March), and maximum temperature on 13 days (10 in February).

The mean absolute daily range of temperature varied from 12·9a. (23°·2F.) in March to 4·9a. (8°·8F.) in December, the mean value for the year being 7·9a. (14°·2F.). In six months, and for the year as a whole, the mean value is greater than the corresponding normal. The greatest daily range was 21·7a. (39°·0F.) on March 28, while the least range was 0·9a. (1°·6F.) on November 30.

In June, August, October, November and December, the range of the mean diurnal inequality is more than 5 per cent. below, and in January, February, March, May and September, more than 5 per cent. above the range of the mean diurnal inequality for the years 1911–26, the greatest positive departure from the normal being 143 per cent. in March and the greatest negative departure 23 per cent. in December.

Humidity.—As is mentioned in the General Introduction, owing to a change in the hygrometric tables used the results from 1926 onward are not strictly comparable with those of earlier years. Compared with the mean values for 1911–25 the chief departures of the values of mean relative humidity in 1929 are +3 in November, −4 in May and −3 in February. The mean relative humidity, 82·8 per cent., for the year is less than that for the other years since 1922 ; whilst the mean vapour pressure, 8·1 mb., is again smaller than in any of the years 1923–8. The extreme daily mean values of relative humidity and vapour pressure were 98·7 per cent. on December 18, 57·3 per cent. on April 20, 16·5 mb. on September 4, 2·2 mb. on February 13. The lowest hourly readings of relative humidity, one of 19 and others below 30 per cent. occurred on March 9.

Precipitation.—1929 was not so wet as the previous three years, the total amount of rainfall, 1611·5 mm. (63·44 in.), being only 6 per cent. over the mean for the period 1911–27. The most outstanding month was December with 327·6 mm. (12·90 in.) or 187 per cent. of normal. The driest month was March with 27·9 mm. (1·10 in.) or 26 per cent. of normal. Precipitation fell, at the rate of not less than 0·1 mm. per hour, for a total period of 1248·9 hours, *i.e.*, in the aggregate for one-seventh of the whole year. The monthly duration was greatest, 194·2 hr., in December, and least 30·2 hr., in March. For the year as a whole the average rate of fall per hour is 1·29 mm. ; the rate of fall during individual months ranges between 1·72 in July and 0·66 in February. The greatest amount recorded during a calendar day was 46·6 mm. (1·83 in.) on November 11. There were 158 days (25 in March) on which either no precipitation was recorded or in amounts too small to be measured. Precipitation amounting to 0·2 mm. or more was recorded on 207 days ; to 1·0 mm. or more on 166 days ; to 20·0 mm. or more on 20 days.

Snow or sleet fell on 46 days, but on no day from May 1 to October 8 inclusive. Observations of " snow lying " at 7h. number 35, 20 of which were in January. There were no large falls of snow.

Sunshine.—The year's total duration of bright sunshine, 1329·1 hr., represents 28 per cent. of the theoretically " possible " duration ; whereas the average percentage of " possible " for the years 1911–26 is 27·1. As regards the percentage of " possible " May was the sunniest, and December the least sunny (as also the wettest) month of 1929. In all, there were 88 days without sunshine, 16 of these being in November, 16 in December and 13 in January, and 95 days with 50 per cent. or more of the " possible " sunshine. The days with most sunshine were June 26 with 14·8 hr. (85·3 per cent.) and July 14 with 14·7 hr. (87·7 per cent.) February 10 with 8·2 hr. (88·8 per cent.) represents the highest value of the percentage of " possible " sunshine.

Wind.—The mean speed for the year, 4·8 m/s (10·7 mi/hr) was less than that for the preceding three years. In comparison with the normal values for individual months the mean speeds for August, October and December exhibit the most considerable excess, and those for January, February and March the greatest relative deficiency. There were only 4 hours of gale force (mean speed greater than 17·1 m/s), the smallest number since records commenced. The highest gust of the year, 29 m/s (64 mi/hr) occurred on September 21, the highest hourly speed, 18 m/s (40 mi/hr) on December 5, and the highest mean daily speed, 12·2 m/s (27·3 mi/hr) on July 10. The quietest days were January 8 and November 14, with mean speeds of 0·5 and 0·6 m/s.

There was a remarkable dearth of westerly winds (between south-south-west and north-north-west) in January and February, and marked scarcity of easterly winds (between north-north-east and south-south-east) from August to October. The predominance of winds from between south and west was greatest in October and December, and the predominance of north-easterly winds was very marked in April.

Grass Minimum Temperature.—There were 129 occasions of ground frost (*i.e.*, grass minimum temperature not greater than 272·1a. or 30°·4 F.), but none of these occurred between June 19 and September 15. The lowest grass minimum temperature was 256·8a. (2°·8 F.) on February 16; other low readings were 257·9a. (4°·8 F.) on January 28, 258·1a. (5°·2 F.) on February 14, and 258·3a. (5°·5 F.) on February 28. The mean grass minimum temperature for each of the months January, February, March, April, November and December is less than 273·0a. (32°·0F.). The mean values for the first four months of the year are about 3a. (6° F.) lower than corresponding values in the previous years.

Cloud and Weather.—(A) The mean amount of cloud observed at the six hours of observation is 7·2 which is the lowest since 1915. August has the largest mean amount, 8·1, and March has the smallest, 4·6, a record since observations commenced. The largest mean amount for an observational hour is 8·8 at 7h in September; the least is 3·0 at 21h in March. For the year as a whole there was most cloud at 15h and least at 21h. In nine months the mean cloud amount was least at 21h, but there was no consistent hour of maximum cloud amount. March 29 is the only day of the year on which no cloud was seen at the normal hours of observation. On 33 days the amount 10 was recorded at every hour of observation.

(B) Thunder was heard on only 7 days, one day more than in 1928. There were observations of solar halo on 8 days, of lunar halo on 13 days, and of aurora or auroral glow on 12 days.

(C) The numbers of occasions on which the range of visibility was estimated to be (1) not greater than 500 metres (550 yards), corresponding with the entries X to E, and (2) at least 20 kilometres (12½ miles), corresponding with the entries k, l, m, are summarized below. The limitations to which the estimates of visibility are subject are mentioned on p. 152. It is to be noted that the group (1) above consists of the occasions which are held to merit the description as "fog, moderate, thick, or dense," while the entries k, l, m, denote "very good or excellent visibility."

There were more occasions of fog and more of estimates k, l, and m together than in 1928. Fog was most frequent in January and March, but entirely absent (at the standard hours of observation) in June. Excepting September, occasions of very good and excellent visibility were most frequent from May to October. There were only 11 estimates of m, visibility 50 km, (31 mi.) or more, distributed among 7 days. 7 of the 11 occasions were at 18h, 8 were associated with increasing barometric pressure, and 9 with winds from west-south-west through north to north-east.

ATMOSPHERIC ELECTRICITY.

Notes on the Instruments.

Autographic records of atmospheric electrical potential gradient were obtained by means of an electrograph of the Kelvin water-dropper type, the potential at the water-jet being registered by a Dolezalek quadrant electrometer. In all essential details the electrograph arrangements, the method of making scale and insulation tests and the method of reducing the autographic curve readings to potential gradient in the open were as described in *The Observatories' Year Book*, 1928, pp. 160-161.

The scale value of the photographic record obtained by means of the Dolezalek electrometer remained at about 3·1 volts per mm. during 1929. One of the levelling screws of the electrometer was adjusted at the beginning of July, and the scale value is slightly increased from July onwards. The number of determinations of the reduction factor (*i.e.*, the ratio of the potential at one metre above the ground in the open to the potential at the water-jet) varied from three in December to twenty-one in March, each determination being based on about fifteen or more readings (at intervals of half a minute) of the potential in the open. At the end of July a scaffolding was erected round the western half of the building in the course of the reconditioning work. This projected some three or four feet beyond the walls and may have affected the equipotential surfaces at the site where absolute observations of potential gradient are made. Subsequently another scaffolding was built round the tower. A small wooden hut erected at the north-west corner of the building may have introduced further complications. The scaffolding was taken down in December but the hut was not removed. The values of the monthly reduction factor finally adopted for 1929 were obtained by a smoothing process, the adopted value for a given month being $\frac{(a + 2b + c)}{4}$, where a, b, c are the unsmoothed monthly mean factors for the three successive months centred in the given month. To avoid smoothing across the discontinuity, the values for July and August were obtained from the formula $\frac{a + 2b}{3}$, where b is the unsmoothed monthly mean factor for the given month, and a is the unsmoothed factor for June in the case of the July factor, and September in the case of the August factor. The final values, which are given in Table 265, range from 6·37 in April to 6·00 in October. The mean of the seven monthly reduction factors from January to July is 6·32, while the mean for the remaining five months of the year is 6·05. The mean for the year is 6·21, as compared with 6·20 for 1928.

All determinations of scale value and reduction factor were obtained with a particular Wulf quartz-thread electrometer. This instrument was calibrated on a number of occasions during the year. Until July the calibrations were in close agreement with that used in 1927 and 1928, and the use of this calibration was continued until July 20. On this day it was discovered that the screw threads on the draw tube of the microscope had been incorrectly engaged in the support, and a readjustment was necessary. A calibration made on July 31 showed a reduction in the sensitivity of about 2·5%. This calibration was used for the determination of scale values of the electrograph and reduction factors from July 22 until December 2. After this date moisture in the instrument impaired the insulation, and the amber insulators were reburnished. A reliable calibration was made on March 14, 1930, and showed an increase of about 4·5% in the sensitivity. This calibration was used from December 3 until the end of the year.

IDENTIFICATION NUMBER OF INSTRUMENT USED IN 1929.

Wulf bifilar electrometer 3040

Notes on the Tables and Results.

As far as possible an electrical character figure is assigned to each day and values of potential gradient are assigned for 3h, 9h, 15h and 21h G.M.T. of all days, while

values for all hours are assigned on days classified as 0*a*, 1*a* or 2*a*. The character figures are given in Table 268, the significance of these symbols being as follows :—

0, denotes a day during which from midnight to midnight no negative potential was recorded.
1, denotes the existence of negative potential at one or more times during the same period, but with a total duration of less than three hours.
2, denotes negative potential extending in the aggregate over three hours or more during the same period.
a, denotes that within the 25 periods of 60 minutes for which an estimate of the mean potential gradient has to be made in the process of tabulation there was in no case a range of potential gradient in the open exceeding 1,000 volts per metre.
b, denotes that, during the same period, a range of 1,000 volts or more per metre was reached in one hour at least but in fewer than six hours.
c, denotes that, during the same period, a range of 1,000 volts or more per metre was reached in at least six hours.

Table 265 contains the values of electrical potential gradient at 3h, 9h, 15h and 21h G.M.T. daily, the value for a given hour representing the mean for the period of 60 minutes centring at that hour. Blanks indicate that the trace was in some way defective. If it is possible to assign an approximate value of the potential gradient on such days, this value is given in brackets. The reduction factors used in converting the potential at the water-jet to potential gradient in volts per metre, in the open, are also given.

In Table 266 are given, for 0*a* days, (1) the mean diurnal inequalities for the months, seasons and year, (2) particulars of the number of days and of the non-cyclic changes and (3) the corresponding mean values of potential gradient. The inequalities or the mean values for the year and seasons are the means of the inequalities or means, respectively, for the appropriate months.

Corresponding data for 1*a* and 2*a* days combined appear in Table 267.

It should be noted that, in these tables, *Winter* denotes the four months January, February, November, December ; *Equinox* the four months March, April, September, October ; and *Summer* the four months May to August.

In addition to the electrical character for each day, Table 268 contains the daily, monthly and annual values of duration (in hours and tenths) of negative potential gradient. 4 days of defective record when negative potential may have occurred are left blank ; the sign of the gradient has been assumed positive during periods of defective records in which no precipitation was observed. If precipitation was recorded for less than an hour during such defective periods an approximate value of the duration of negative potential for that hour has been assigned, and the total for the day given in brackets. When, during highly oscillatory gradients, there was uncertainty as to the times of changes of sign, half of the total duration of doubtful sign was accounted negative. The total duration of negative potential gradient in each month and the average daily duration are entered in the lower part of the table. For the 361 days of assignable duration of negative potential gradient the total number of hours was 697·4 as compared with 1006·0 in 1928 ; an average of 1·93 hours per day, as against 2·89 hours per day in 1928.

Following the practice adopted in 1923 the mean values of potential gradient given in Table 265 are of two kinds, viz., (*a*) the mean of all the positive values of potential in the column and (*b*) the algebraic mean derived from all days on which all four hours were represented. The mean values for the month, as derived from the

(*a*) and (*b*) values respectively, are shown in the last line, and the means for the year are given at the foot of the December table. It is to be expected that the mean derived from the values at 3h, 9h, 15h and 21h, on a sufficiently large number of days, will approximate closely to the mean value derived from all hourly values of all the days.

The (*a*) mean exceeds the (*b*) mean, and is exceeded by the mean value on 0*a* days, in all months of the year. The general tendency is for the 1929 values to exceed those of 1928, this being the case in eight months for the (*a*) mean, and eleven months for the (*b*) mean.

Annual mean values for recent years, derived by giving equal weight to the twelve monthly means, of the (*a*) and the (*b*) means and of the means for 0*a* days are as follow :—

	0*a* v/m.	(*a*) v/m.	(*b*) v/m.
1922	257	225	182
1923	278	235	159
1924	236	214	157
1925	284	243	209
1926	249	201	177
1927	259	223	193
1928	237	219	150
1929	276	240	216

Each of the three mean values for 1929 is greater than the corresponding value for 1928 and is close to the corresponding value for 1925. The highest values of all three means occurred in March, a month of fine, dry weather associated with an anticyclone which extended over the British Isles for a prolonged period.

Noteworthy occasions of high potential gradient were as follow :—

(i) January 18d 10h 20m to 20h 40m. The mean potential gradient during this interval was 800 v/m., and was associated with wet fog or slight drizzle.

(ii) January 22d 12h 20m to 19h. High potential gradient during fog or mist. The mean for this period was about 1100 v/m.

(iii) February 8d 23h to 9d 8h 20m. High potential gradient during wet fog. The mean value for the whole interval was about 900 v/m.

(iv) March 2d 17h 20m to 3d 6h 30m. During this period the mean potential gradient was about 750 v/m. This was a cold, fair night with little or no wind.

(v) March 7d 17h 20m to 22h 10m. A mean potential gradient of about 1000 v/m. was attained on a clear frosty night.

(vi) March 18d 17h 30m to 19h 5m. The mean potential gradient during this period was about 900 v/m., and was associated with a clear frosty night.

The following were the noteworthy occasions of continuous negative potential gradient :—

(i) May 4d 16h 30m to 23h. This was a period of heavy rain followed by moderate rain. Precipitation was continuous at first but intermittent in the last hour. Values below —1400 v/m. were reached, but not for prolonged spells.

(ii) October 23d 17h 40m to 24d 1h 30m. In this interval during which continuous rain fell, the mean potential gradient was about −800 v/m. Occasionally the limits of registration (−1300 v/m) were exceeded, but not for more than five minutes at a time.

(iii) November 11d 3h 40m to 15h. More than eleven hours of continuous negative potential gradient during which continuous rain fell. The limit of registration was exceeded, for four periods, each lasting from thirty to forty minutes.

(iv) December 2d 6h 40m to 14h. During this period continuous rain fell and the negative potential gradient was about −1000 v/m. Occasionally values below −1300 v/m were reached, but only for a few minutes at a time.

(v) December 20d 19h to 21d 3h 50m. This was a period of continuous snow preceded by sleet. For six and a half hours the potential gradient was less than −1300 v/m, except for one excursion, lasting about five minutes, to −1000 v/m.

(vi) December 24d 2h 20m to 5h 40m. The potential gradient was continuously less than −1200 v/m for three and a half hours. Continuous rain fell during this period. Later when this became drizzle the sign of the potential gradient reverted to positive.

On the following occasions long periods of negative potential gradient were broken by short excursions to the positive side :—

(i) July 31d 2h 45m to August 1d 12h. During continuous rain, heavy at times, the potential gradient was negative and highly oscillatory, except for excursions to the positive side associated with large oscillations during heavy rain. Following this interval was a succession of three excursions to the negative side of varying amplitude, corresponding to showers, and a single large oscillation to the positive side to +1400 v/m.

(ii) December 7d 0h 30m to 7d 40m. During light rain the potential gradient consisted of long period oscillations on the negative side with ranges exceeding 1300 v/m. During one of the oscillations there was an excursion to the positive side when a value of +150 v/m was reached.

(iii) December 25d 13h 30m to 26d 3h. During continuous rain the potential gradient consisted mainly of short period oscillations on the negative side. Towards the close of this interval the limit of registration was exceeded for about an hour. The continuity of negative gradient was broken by a short spell of positive for four minutes in the middle of the period, and a spell of fifteen minutes near the end of the period during which a double oscillation on each side of the zero occurred, the values of the maxima in each oscillation being +200 v/m. and +600 v/m.

(iv) December 28d 14h 20m to 25d 2h 30m. During this interval slight sleet fell followed by continuous heavy rain. In the first part of the period the potential gradient was lower than −1300 v/m for two hours and a half except for about twenty-two minutes, when in a double oscillation maxima of −530 v/m and −780 v/m occurred. During the latter part of the period the gradient consisted of short period oscillations of small amplitude, values less than −1300 v/m being attained occasionally.

About 23h the potential gradient rose in a series of small oscillations about an ever increasing mean to +100 v/m. This was immediately followed by a more rapid decrease to −1300 v/m after which the potential gradient resumed its earlier character of short period oscillations with occasional excursions below −1300 v/m.

Although there are considerable irregularities in the mean diurnal inequalities of potential gradient on 0*a* days for individual months, the mean inequalities for the seasons resemble fairly closely the normals for 1913–23. As is usual, the principal minimum in winter occurs in the early morning, and the principal maximum at 19h. The tendency towards a small secondary maximum before noon, and a small secondary minimum after noon, is not so clearly shown as in most years. In the mean diurnal inequality for the four equinoctial months the chief features are a minimum at noon and a maximum at 20h. In the summer inequality the minimum occurs about noon, though there is little difference between the values from 11h to 13h, and the chief maximum at about the normal time, viz., 21h. The secondary maximum at 7h is largely due to the occurrence of the principal maximum for May and August in the early morning, but the feature is present in the inequalities for each of the other two months. The secondary minimum at 3h is more clearly defined than usual.

TERRESTRIAL MAGNETISM.

Notes on the Instruments.

The standard magnetographs,[1] which have been in regular use since 1909, are situated in the east chamber of the underground magnet house and are arranged so as to record changes of the three geographical components of terrestrial magnetic force, viz., the north component, N (or + X), west component, W (or − Y), and the vertically downward component, V (or + Z).

The instruments for the north and west components are of the Adie bifilar type, in which torsion of the bifilar suspension, of fine tungsten or steel wire, is utilised to bring the magnets into an azimuth approximately perpendicular to the directions of the components whose changes they respectively record. In each of these instruments the magnet is about 13·8 cm. in length and is suspended within a copper shell, or frame, of suitable dimensions to ensure that the movements of the magnet are sufficiently damped. To the magnet is rigidly attached a semi-circular plane mirror, immediately beneath which is a fixed mirror of similar form and dimensions. Each magnet and mirror system is contained within a brass cylindrical case, cemented on to a pier and surmounted by a tall bell-jar shaped cover of glass. Light from a brightly illuminated slit passes through a collimator, is incident upon the two mirrors and after reflection passes along a wooden channel and thence, through a horizontal hemi-cylindrical lens, to photographic paper wound on a clock-driven cylinder. The hemi-cylindrical lens is set in the side of the case containing the recording drums, and matters are so arranged that the beams of light reflected from the two mirrors are brought to a focus by the lens which condenses the two vertical images to two sharply focussed dots on the paper. Hence the record obtained consists of two traces, the one straight and known as the base line, the other curved and representing the angular movements of the suspended magnet, and, therefore the changes in the component of terrestrial magnetic force.

The standard instrument for the vertical component is a Watson multiple-magnet balance.[2] In this instrument the magnet system consists of eight magnetised steel rods, each 10 cm. long and 0·2 cm. in diameter, carried by an aluminium frame to the centre of which are attached the moving mirror and also the knife-edge, which

[1] For a general description of magnetograph arrangements see "A Dictionary of Applied Physics," Vol. II, Macmillan, London.

[2] Terrestrial Magnetism, Vol. VI.

bears upon an agate plane and about which the system balances. Copper damping plates and a temperature-compensating device are provided. The recording arrangements are similar to those described above, save that the hemi-cylindrical condensing lens and the recording drum are vertical.

One clock serves to operate the three drums and also makes the time marks at two-hourly intervals.

To the containing case of each instrument is fitted a suitably designed drying tube containing calcium chloride.

Determinations of the azimuth of the magnets of the north and west component magnetographs are carried out, at intervals of a year or two, by comparing the deflections produced by an auxiliary magnet with its axis (*a*) true north-south, or east-west and (*b*) inclined at a known small angle to those azimuths. Drift of the magnet system of the Watson balance has been compensated from time to time by adjusting the position of a small control magnet which is fixed vertically to the lower part of the pier on which the balance stands. The Watson balance was cleaned on June 11 and the drying material renewed. The scale value was thereby decreased from 4·20 to 3·91 γ/mm.

The azimuth lines in use in the east chamber are those which were determined in 1914 and of which particulars are given on p. 70 of *Hourly Values from Autographic Records, Geophysical Section*, 1913.

The diurnal range of temperature in the east chamber of the magnet house is normally negligible. Temperature is ascertained daily at 9h 30m by the thermometers within the instrument cases. The daily values appear in Tables 272, 276, etc.; the monthly means of the readings so obtained during 1929, together with the mean values for the years 1911–1928, were as follow:—

EXCESS OF MEAN TEMPERATURE ABOVE 280a.

Month.	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Mean 1929 ..	3·5	2·6	2·0	2·2	2·5	3·4	4·9	5·2	5·6	5·4	4·8	3·9
Mean 1911–28 ..	3·6	3·0	2·7	2·5	2·8	3·7	4·7	5·8	6·4	6·3	5·6	4·6

The annual range of temperature during 1929 was 3°·8 C., the mean range for the previous seventeen years being 4°·2 C.

The constants of the standard magnetographs were as follow:—

	North.	West.	Vertical.
Time scale .. .. 1 hour =	15·5 mm.	15·5 mm.	15·5 mm.
Time marks	Every two hours, beginning at exact hour.		
Error of time mark	Not more than ± 1 min.		
Period of vibration, seconds	13·9	9·9	7·4
Logarithmic decrement[1]	·365	·569	—
Angular equivalent of 1 mm. on paper, radians ..	·00032	·00032	·0003
Twist of bifilar suspension	60°	30°	—
Ratio $\frac{\text{length of bifilar suspension}}{\text{mean breadth of suspension}}$	66	100	—
Temperature coefficient, per 1° C.	−9 γ	−2 γ	+26 γ
Direction of marked pole	West.	North.	—
Azimuth of magnet	270°	0°	346°

[1] Log. decr. $= \text{Log}_e a_n - \log_e a_{n+1}$; where a_n, a_{n+1} are the amplitudes of two successive swings on the same side of the zero position.

Determinations of scale value of the standard magnetographs are carried out at intervals of two weeks. The method adopted consists essentially in measuring the photographically recorded deflection of the suspended or pivoted magnet produced by an auxiliary or test magnet of known magnetic moment situated at a known distance from the deflected magnet. Two sets of relative positions of the deflecting and deflected magnets are used; for the north and west instruments they may be termed the "end on" and "broadside on" positions, the magnet axes being in one plane: while in the case of the vertical instrument the deflecting magnet is vertical; in one position the line joining its centre to that of the deflected magnet is collinear with the axis of the latter, but in the other position it is perpendicular thereto. On a given occasion deflections are produced with the test magnet first on one side of the deflected magnet and then, at the same distance, on the other side, two deflections being produced at each side by reversal of the test magnet. Thus four deflection dots are obtained on the record. The two sets of relative positions of the magnets are employed on alternate occasions. The distance between the deflected and deflecting magnets is about 90 cm., and approximate values of the double deflections produced are 44 and 87 mm. for the north instrument, 33 and 65 mm. for the west, and 51 mm. for the vertical. In deducing the scale values allowance is made for the distribution of magnetism in the magnets by assuming that the latter consists of point poles separated by four-fifths of the length of the steel[1] and thence computing values of P, the distribution coefficient, for the different relative positions of the magnets. The moment of the auxiliary or test magnet is determined at intervals of about one month by deflections at two distances on the Kew magnetometer, the value of the horizontal component of the earth's field being obtained from the result of an absolute observation made on the same day.

In the following table are given the scale values, obtained by overlapping means, which were employed in reducing the curve readings for 1929.

SCALE VALUES OF THE MAGNETOGRAPHS (γ per mm. on the paper).

Month.	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
North Instrument ..	5·06	5·06	5·07	5·05	5·06	5·04	5·04	5·04	5·05	5·07	5·07	5·07
West Instrument ..	6·67	6·67	6·68	6·70	6·69	6·67	6·65	6·67	6·69	6·71	6·73	6·71
Vertical Instrument ..	4·23* / 4·33	4·33	4·29	4·28	4·23	4·20† / 3·91†	3·92	3·95	3·97	3·97	3·96	3·96

* 4·23 γ/ mm. to 28d 9h 30m., 4·33 γ/ mm. from 28d 9h 30m.
† 4·20 γ/ mm. to 11d 9h., 3·91 γ/ mm., from 11d 10h.

In addition to the standard magnetographs there are in the west chamber of the underground magnet house auxiliary instruments of the Adie pattern (formerly the standard instruments at Kew Observatory) which record changes in declination, D, horizontal force, H, and also vertically downward force, V. Declination records have been obtained since August, 1927, while the vertical force (Adie) and horizontal force records commenced in March and December, 1928. The general arrangements of these instruments are similar to those of the instruments in the east chamber. The declination magnet is suspended by a bundle of silk fibres (the torsion effect of which is negligible) and the scale value of the record if 1′·17 to 1 mm. The vertical force balance consists of a single magnet, of which the dimensions are approximately 13·5 cm. × 2 cm. × 0·2 cm. With the object of reducing loss of record during magnetic storms the scale values of the auxiliary H and V records are arranged to

[1] Chree, Phil. Mag. 1904.

be considerably greater than those of the standard N and V records. Thus, in the earlier part of 1929 the scale values of the Adie H and V records were approximately 10γ and 9γ per mm. respectively. Determinations of scale value are made by the method due to Broun. To facilitate the necessary adjustment, from time to time, of the azimuth of the horizontal force magnet, magnetic meridian lines (and lines perpendicular thereto) representing a sufficient range of values of declination were laid down in the west chamber in December, 1928 on the basis of simultaneous observations of declination in the chamber and in the east magnetic hut.

The routine absolute observations of the magnetic elements are made in the east magnetic hut; as a rule two complete sets of observations are made every week, but in 1929 a determination of declination was made on nearly every week-day. Declination and horizontal force were determined by means of the Kew pattern unifilar magnetometer (which was employed by Rücker and Thorpe in their magnetic surveys of the British Isles, 1886–1892) placed on Pier No. 5. Determinations of inclination (dip) are made by means of the Schulze inductor placed on pier No. 6.

For a detailed description of the method of observation with the Kew pattern magnetometer reference should be made elsewhere.[1]

In determining declination four readings are taken, two with the magnet erect, two with the magnet inverted. A correction is applied to the mean of the observations for the observed torsion in the silk suspending fibre. The fixed mark is about one half-mile (0·8 km.) distant from Pier No. 5, and its bearing is taken as 8° 12′ 30″ west of south.

Determination of the horizontal intensity comprises observations of (*a*) the time of vibration of the collimator magnet, and (*b*) the deflection of a mirror magnet by the collimator magnet. Deflection observations are made for three distances of the collimator magnet, the order of the position of the latter being: on east arm at 35 cm., 30 cm., 25 cm.; on west arm at 25 cm., 30 cm., 35 cm. Thus the mean times for the deflections at the three distances are very nearly, if not exactly, identical and the observations are concentrated at the 25 cm. distance. The time interval between the mean times of the vibration and deflection experiments is usually about half an hour. The horizontal intensity, H, is calculated from $H=\sqrt{mH_V \times H_R/m}$ where mH_V is obtained from the vibration experiment and H_R/m from the deflections made at the 25 cm. distance, m being the moment of the collimator magnet. H_R/m is corrected for the distribution of magnetism in the magnets. From the latter part of 1913 until the end of 1923 the value of this correction, viz., $\log_{10}(1+P/25^2+Q/25^4)$, applied to the observations of a given month was a mean value derived from the observations obtained during the seven months including the given month as fourth of the seven. The monthly values so derived show considerable fluctuations, and it is improbable that P and Q actually varied to the extent implied. Commencing in 1924 the value of the correction used in reducing the horizontal intensity observations has been the mean of the mean values for each of the years 1917–24, 1917–25, etc. The value employed for 1929 is ·00541. The mean value of the logarithm for the years 1917–29 is ·00543. Had this value, instead of ·00541, been used in reducing the observations for 1929 the published values of H, N, W and V would be increased by 0·4, 0·3, 0·1 and 1·0γ, respectively. A variation of ·00020 in the value of $\log_{10}(1+P/25^2+Q/25^4)$ corresponds with a variation of about 4γ in the derived value of H.

[1] Dict. of Applied Physics, Vol. II, p. 532 *or* Stewart and Gee's "Practical Physics."

The values of P, Q, and $\log_{10}(1+P/25^2+Q/25^4)$ for individual years are as follow :—

Year.	P.	Q.	$\log_{10}(1+P/25^2+Q/25^4)$.
1917	+ 6·862	+ 418·9	·00520
1918	+ 7·604	+ 68·6	·00533
1919	+ 9·126	− 603·5	·00563
1920	+ 8·224	− 216·6	·00544
1921	+ 7·978	+ 25·3	·00554
1922	+ 6·607	+ 513·1	·00513
1923	+ 6·371	+ 614·3	·00508
1924	+ 7·899	− 128·6	·00531
1925	+ 8·214	− 261·7	·00538
1926	+ 9·675	− 938·4	·00564
1927	+10·422	−1265·0	·00580
1928	+ 8·713	− 547·2	·00541
1929	+ 9·741	− 917·4	·00571

The Schulze inductor[1] consists essentially of a coil of insulated wire which can be rotated continuously and rapidly about an axis which coincides with a diameter of the coil. This axis is capable of rotation about a horizontal and vertical axis. The inclination and azimuth of the coil axis are read off on a vertical and a horizontal scale respectively. The windings of the coil are led off from a commutator to a Broca galvanometer. To effect a determination of magnetic inclination, the coil is set so that its axis of rotation lies in the plane of the magnetic meridian. The coil is then rotated steadily at the rate of about 360 revolutions per minute and the inclination of the axis of rotation is adjusted until the galvanometer deflection is the same in magnitude and sign whether the sense of rotation is positive or negative. In this position the rotation axis of the coil coincides with the direction of the earth's field and the inclination to the horizontal may be read off from the vertical circle. Two series of settings are made, one with the vertical circle facing east, the other with the circle facing west.

The base line values of the magnetograph records are deduced from the results of the absolute observations, any of the latter obtained during times of considerable disturbance being excluded. For a set of absolute observations on a given day the mean ordinates of the north and west component curves are determined for the periods of time corresponding to the declination, the vibration, and the 25 cm. deflection observations.

From these values, and from the value of H obtained as described above, the value of H corresponding to the mean ordinates during the declination observation is derived, and thence the base line values of N and W are computed. Similarly, by the combined use of the curve ordinates at the times of the inclination and horizontal force observations the value of H corresponding to the inclination observation is obtained and thence the base value for V. The base line values finally adopted are obtained from a curve drawn smoothly through points given by the deduced values, due allowance being made for discontinuities in the records.

The results of the absolute determinations of D, I and H are summarized in the subjoined table, and the values of *m*, the moment of collimator magnet 60a, are also given. For each set of absolute observations are shown the deduced base line values of N, W, and V and, in brackets, the adopted base line values. Thus, the entry 15823 (18) signifies :—deduced base line value 15823, adopted base line value 15818. The adopted values were obtained as described in the foregoing, and therefore the base line values corresponding to dates between those given in the table may be obtained by interpolation.

The hourly readings are obtained from the magnetograms, standardized as described in the foregoing, by means of a ruled glass scale. The reading for any given hour G.M.T. is that ordinate estimated to be the mean reading for 60-minutes centring at the given hour. The product of this ordinate and the scale value is added to the adopted base line value, and the sum so obtained is the hourly value printed in the tables.

IDENTIFICATION NUMBERS OF INSTRUMENTS IN USE IN 1929.

Unifilar Magnetometer, Kew pattern .. .. .. Elliott, No. 60.
(with collimator magnet, 60a, and mirror magnet, 60c).

Dip Inductor .. .. Schulze, No. 103.

Notes on Tables.

The hourly values of N, W, and V, obtained as described above, appear in three of the four monthly tables. The mean value for the day is computed according to the expression

$$x = \{\tfrac{1}{2}(x_0+x_{24}) + x_1+x_2 + \ldots\ldots\ldots + x_{23}\}/24.$$

The letters " Q " and " D " denote the five quiet and the five most disturbed days as selected at De Bilt.

In the fourth table for each month are given :—

(*a*) the values and times of the daily maximum and minimum and the values of the absolute daily range for each of the components N, W and V.

(*b*) the value of ΣR^2 for each day. ΣR^2 is written for $R_N^2+R_W^2+R_V^2$ where R_N, R_W, R_V denote the absolute ranges for a calendar day of the north, west and vertical components.

(*c*) the daily magnetic character figures, assigned according to the international scheme wherein " 0," " 1," " 2," respectively, denote quiet, moderately disturbed, and highly disturbed conditions.

(*d*) the daily values of temperature in the underground magnetograph chamber.

In *The Observatories' Year Book* for the years 1922–6 the fourth table for each month contains the values of the " characteristic ratio," ρ, which is the ratio of the value of ΣR^2 for a given day to the mean monthly value of ΣR^2. To some extent this ratio serves as an index of the degree of disturbance on a given day relatively to other days of the same month. It enables the most highly disturbed days to be identified with fair certainty, but is of less use in distinguishing between the quieter days of a month, especially in summer months, when even the quiet day range is large, and in months in which very large disturbance occurs. Another defect is the great difference in the significance, in different months, of one and the same value of the ratio. Further, as long as record is liable to be lost during the larger disturbances the exact value of the ratio cannot be computed in some cases. Some of the drawbacks mentioned could be diminished by relating the ratio of the daily value of ΣR^2 not to the mean value of ΣR^2 for the month but to a quantity which approximates to the mean value of ΣR^2 for a long period, *e.g.*, for 11 years. It is considered that, on the whole, the applications of ΣR^2 as a criterion of disturbance or activity is not materially increased by the publication of the values of "ρ," and it was decided as from 1927 to discontinue the publication of this ratio.

Hourly values of declination are not given in this volume. They have been published weekly, primarily for the use of mine surveyors, in " The Colliery Guardian " and " The Iron and Coal Trades Review."

Mean diurnal inequalities of the components N, W, V, H, D, and I on " all " days and on international quiet and disturbed days are given, for the months, seasons and year, in Tables 317 to 334. In calculating diurnal inequalities the non-cyclic change has been eliminated on the assumption that its time-rate is linear. Inequality values are first calculated to $0{\cdot}01\gamma$ and then rounded off to $0{\cdot}1\gamma$. The inequalities of H, D, and I have been computed from those of N, W, and V, by means of the formulæ :

$$\delta D = \frac{180\times 60}{\pi}\left(\frac{\delta W\cos D - \delta N\sin D}{H}\right)$$

$$\delta H = \delta N\cos D + \delta W\sin D$$

$$\delta I = \frac{180\times 60}{\pi}\cos I\left(\frac{\delta V\cos I - \delta H\sin I}{H}\right)$$

in which δD and δI are expressed in minutes of arc, and where H, D, and I for any given month are the respective mean values for that month as published in Table 338. The values of the range of the mean diurnal inequalities of the several elements on the three different types of day are brought together in Table 335, and the values of the non-cyclic change of N, W, and V are given in Table 336.

The results of harmonic analysis of the mean diurnal inequalities of N, W, and V for the months, seasons[1] and year are to be found in Tables 339 and 340, in which are given the values of a_n, b_n, c_n, and α_n, in the two equivalent series $\Sigma\ (a_n \cos 15nt^\circ + b_n \sin 15nt^\circ)$ and $\Sigma\ c_n \sin (15nt^\circ + \alpha_n)$. In the former series t is reckoned in hours from midnight G.M.T., whilst the published values of α_n refer to Local Mean Time. The values of the harmonic coefficients have been computed from the unrounded values of the inequalities and have been corrected, where necessary, on account of the fact that the hourly values are not instantaneous values but are mean values. The factors by which the coefficients have to be multiplied (*vide* Report of the British Association, 1883, p. 98) are 1·00286 for a_1, b_1, c_1; 1·01152 for a_2, b_2, c_2; 1·02617 for a_3, b_3, c_3, ; and 1·04720 for a_4, b_4, c_4. Finally, the values were rounded off to 0·1 γ.

The mean values of the squares of the absolute daily ranges are summarized in Table 337.

In Table 338 appear for the months and year the mean values of N, W, V, D, I, H and Total Force, T. The means of the four latter elements are derived from the corresponding mean values of N, W and V, which are the means of hourly values on "all" days in the month or year. Tables 341 and 342 contain mean values of the magnetic elements for 1929 and recent years at a number of observatories.

Review of Results of Magnetic Observations.

Mean and Extreme Values of the Magnetic Elements, 1929.—The mean values[2] are given below in Table I along with the corresponding values for the previous year. The values of N, W, and V have been computed from the hourly values derived from the autographic records of "all" days, standardized by means of the absolute observations; those of H, D, I, and T have been deduced from the values of N, W, and V.

TABLE I.

Year.	H.	D. (West).	I.	N.	W.	V.	T.
	γ	° ′	° ′	γ	γ	γ	γ
1928	16619	15 10·5	69 41·2	16039	4350	44894	47871
1929	16603	14 58·9	69 41·9	16038	4292	44878	47851

Westerly declination was on the average 11′·6 less in 1929 that in 1928. The rate of decrease is slightly less than the average rate, 12′·4, during the years 1920–27. Between 1913 and 1920 the average rate of decrease was 9′·3. As compared with the 1928 value horizontal force shows a fall of 16γ, which is greater than the average annual rate of decrease between 1912 and 1927. Practically no change in the average value of the north component has occurred since 1925, but as in recent years the west component decreased by some 60γ. Inclination has increased by 0′·7. The values of vertical and total force obtained for 1929 are slightly less than those for 1928.

Mean values derived from (*a*) international quiet days and (*b*) international disturbed days are as follow: (*a*) N, 16042γ; W, 4293γ; V, 44878γ; (*b*) N, 16031γ; W, 4291γ; V, 44877γ.

[1] The seasons are defined for this purpose as follows:—*Winter*, January, February, November, December; *Equinox*, March, April, September, October; *Summer*, May, June, July, August.

[2] See remarks on p. 168.

The differences between the mean annual values of N, W, and V, derived from "all," international quiet, and international disturbed days in 1926, 1927, 1928 and 1929, are given below, together with the mean differences for the years 1915–1925. In every year of the series quoted the mean value of N and of W on quiet days exceeded the mean value on "all" and on disturbed days The only years in the period 1915-25, for which either the "all" or the disturbed day mean value of V exceeded the quiet day value were 1917, 1919, 1921.

	Quiet day mean—"All" day mean.			Quiet day mean—Disturbed day mean.

The resultant vector representing the average excess of the mean values on "all" days over the mean values on quiet days, for the years 1915–1925, has a magnitude of 3γ; its azimuth is 156°, measured from true north through east, and it is inclined at about 77° to the upwardly directed vertical. The vertical plane which contains this vector approximates very closely in azimuth to the vertical plane passing through Eskdalemuir and the pole (taken as 78°N, 68°W) of the axis of magnetization of the earth. (cf. S. Chapman, *On certain average characteristics of world-wide magnetic disturbance.* Lond. Proc. Roy. Soc. Series A. Vol. 115, p. 242).

The extreme values of N, W, and V recorded during 1929 are given in Table II.

Magnetic Character of the Year.—General agreement not having been reached yet as to the most suitable method of obtaining a numerical measure of magnetic activity, the Eskdalemuir practice of tabulating for each day the value of ΣR^2[(1)], *i.e.*, the sum of the squares of the absolute daily ranges of N, W and V, has been continued. The evaluation of the mean daily values of Σr^2, the sum of the squares of the hourly ranges of N, W, and V, has not been carried out since 1925, but the values of hourly ranges have been tabulated and are available for the purposes of investigation. The magnetic character figures which were assigned in accordance with the international scheme are summarized in Table III. These character figures were assigned quite independently of knowledge of the values of ΣR^2. Table III contains also the monthly mean value of the international character figures, which for 1929 are based on the estimates made at 41 observatories, and the mean monthly values of ΣR^2 for "all," "0," "1," "2," international quiet (Q), and international disturbed (D) days.

(1) See p. 169.

The Eskdalemuir mean character figure for the year is slightly less than for 1928, though the international mean character figure is greater; in fact it is the highest during the present sunspot cycle. The mean sunspot numbers for the years 1923–29 are, in order, 5·8, 16·7, 44·3, 63·9, 69·0, 76·8 and 64·2. Both the Eskdalemuir and the international mean character figures increased concurrently with the sunspot numbers up to 1926, but the concurrence since then has not been maintained.

The Eskdalemuir character figures suggest that March was the most disturbed month, but on the basis of mean values of ΣR^2 it will be seen that February stands higher, higher even than the very disturbed months of October, 1926, and July, 1928. According to either criterion January was the quietest month.

In Table III the annual mean values are the means of the monthly values entered in the corresponding columns. If equal weight be allowed to individual "2" days, the mean annual value of $\Sigma R^2/100$ on these days is 2215. The mean value of ΣR^2 for all days is considerably less than in 1926; it exceeds the value for any of the other years since 1919. In the months February, July, August, November and December the value of ΣR^2 on all or D days is greater than in 1926.

Diurnal Inequalities.—The mean diurnal inequalities for "all" days, international quiet and disturbed days, for the months, seasons and the year, are given in Tables 317–334, and the corresponding inequality ranges in Table 335. The inequalities of N, W, and V for international quiet and disturbed days are shown graphically in Plates III and IV, the representation in the latter plate being in the form of vector diagrams.

The ranges of the mean diurnal inequalities of N, W and V on all days in 1929 are in the main smaller than in 1928 and about equal to those of 1927; but in February, March and December the V ranges are much larger than those of the two previous years and equal or exceed those of 1926. The same may be said of disturbed days. On quiet days there is not so much variation from year to year and in 1929 the ranges are, as usual, greatest in summer and least in winter.

The average values of the diurnal inequality ranges for the year and seasons for the period 1916-26 (not the values of the range of the representative mean diurnal inequalities for this period) are given below, along with the 1929 values expressed as a percentage of the average values. The units employed are 1γ for force and 1′ for declination. The mean sun-spot number for 1916-26 is 46·7; that for 1927 is 69·0, for 1928 76·8, and for 1929 64·2. The 1929 values are nearly all above the average, the excess being greatest in winter. The most conspicuous deficiency is H for disturbed days in equinox.

The values of the mean daily range for the year are slightly greater than for 1928 and 1927 but less than the corresponding values for 1926. The mean ranges for the winter season are greater in all components than for many years past, but the ranges for the summer are less than those of recent summers.

The frequency distribution of absolute daily ranges recorded in 1929 is shown in Table V, which also contains the percentage distribution for the period 1916–1926.

Table VI.—Principal Magnetic Disturbances Recorded at Eskdalemuir, 1929.

Where the beginning of a disturbance has been marked by a "sudden commencement," the serial number is followed by an asterisk (*), and the time entered in the second column is that of the sudden commencement, estimated to the nearest minute. In other cases, the exact hour nearest the time at which disturbance may be regarded as having begun is entered in the second column. To the tabulated values of maximum and minimum the following have to be added:—N, 15000 γ; W, 4000 γ; V, 44000 γ.

The intervals of maximum frequency in 1929 are 70–79γ for N, 60–69γ for W, and 20–29γ for V. These are the same as in 1926 and 1927, but in 1928 the maximum frequency for W was about one interval higher. In 1923, the year of the last sunspot minimum, the intervals were 40–49γ for N and W, 10–19γ for V.

On 50 days in 1929 the absolute range in either N or W was 160γ or more. The numbers of such days in the years 1915 to 1928 were, in order, 30, 47, 35, 56, 58, 36, 27, 32, 11, 10, 24, 46, 41, 48. The frequency of occurrence in 1929 of ranges in excess of 199γ is about one-half that in 1926 and much the same as in 1927 and 1928. There were nine days on which the range in each of N, W, and V was 200γ or more, as compared with 18 such days in 1926, seven in 1927, and five in 1928.

Irregular changes in Declination.—In connexion with the supply of declination data to mine surveyors it has been the practice to classify the hourly periods between the exact hours G.M.T. into four groups according to the range in declination within each period. The range limits, which were adopted in consultation with representative mine surveyors, are :—less than 5′, between 5′ and 15′ between 15′ and 30′ and greater than 30′. This method of classification has been applied to the declination records obtained in the year 1929 and the actual frequencies of occurrence of hourly ranges in the last three of the four divisions mentioned are set out below. Owing to defects in the record ranges could not be assigned in the intervals January 3d 10h–3d 12h, February 16d 6h–16d 9h, June 10d 10h–10d 16h, July 6d 4h-6d 9h, August 1d 10h–1d 16h, 1d 19h–1d 21h, 2d 5h–2d 10h, 3d 2h–3d 9h, September 5d 2h–5d 6h, September 28d 18h–28d 20h. A range of 30′ is equivalent to a change of 145γ in the component of horizontal force perpendicular to the magnetic meridian.

Number of cases per month.

On the average quiet day the most conspicuous change in declination is that from the most easterly value at about 8h or 9h to the most westerly value at about 13h or 14h ; the rate of change being greatest between 10h and 12h. The hourly range due to the regular diurnal variation at this time of day is less than 5′, but doubtless it happens at times that the occurrence of slight disturbance will result in the hourly range exceeding 5′, whereas the occurrence of the same degree of irregularity at another hour of the day would not cause the hourly range to exceed 5′. Thus the figures given above for the range interval 5′–15′ tend to exaggerate somewhat the incidence of irregular changes between 9h and 13h. The hourly distributions of the frequency of occurrence of ranges between 5′ and 15′ and between 15′ and 30′ exhibit the well known tendency for irregular changes to occur predominantly during the " night " hours—at least in Europe. Ranges in the first interval were nearly twice as frequent and in the second interval six times as frequent, between 16h and 4h as between 4h and 16h.

Principal Magnetic Disturbances during 1929.—Particulars of the principal magnetic disturbances recorded during the year are given in Table VI. Corresponding information for the same disturbances is given in the Lerwick Section. The magnetograms for the most highly disturbed days are not reproduced in this volume, but photographic copies may be obtained on application to the Director, Meteorological Office, Air Ministry, Kingsway, London, W.C. 2.

Remarks on Magnetic and Allied Phenomena, 1929.

January.—(Average Character Figure 0·61). One or two minor disturbances took place in the first half of the month. The first was ushered in by a "sudden commencement" at 5d 3h 7m and during the evening of the same day there were irregular oscillations in N and W, accompanied by a hump of about 55γ in V, with a maximum soon after 19h. At 8d 21h 28m a small rise in N and W marked the beginning of another disturbance which did not completely die away until the 11th. The first movements consisted of irregular dips in all components, with minima at about 9d 1h; during the rest of the 9th the movements were small and irregular, with temporary increases of activity about 18h and 22h. Slight agitation continued during the 10th and the early hours of the 11th.

Apart from minor activity on the 14th the rest of the month was quiet and on no day during the month was a range of 200γ attained in any component.

The large group of sunspots in solar latitude 7°N which passed the central meridian of the sun on Jan. 17·4d[1] was not apparently associated with any magnetic disturbance, nor was the spot in latitude 11°S which passed the meridian on Jan. 21·8d.[1]

February.—(Average Character Figure 0·86). Quiet conditions persisted until the 6th; the 6th—10th inclusive were rather more disturbed, but were followed by another quiet period until the end of the 16th. Small but well-marked movements took place in all components at about 9d 18h and were repeated in very similar shapes and amplitudes shortly after 10d 16h, *i.e.*, at an interval of about 22h.

Following a "sudden commencement" at 16d 15h 7m a considerable disturbance took place on the 17th. Very small and rapid oscillations occurred from 16d 14–18h; after a quiet period these were renewed at 23h 10m, and irregular fluctuations took place in all components during the early hours of the 17th. The disturbance increased in intensity during the afternoon; in the horizontal components the fluctuations were irregular and the long-period oscillations not much in evidence, but in V the curve shows a large hump between 12h and 21h, and a dip from 22h till 18d 6h; these are separated by a rapid fall of 180γ in 13 mins., beginning at 17d 20h 27m. The ranges during this part of the disturbance were:—N, 306γ; W, 253γ; V, 407γ.

At Lerwick the disturbance in H attained four times as great a range as at Eskdalemuir, and the Lerwick H trace resembles the Eskdalemuir V trace.

The succeeding days were marked by continuous minor disturbance until 24d 20h, when conditions became quiet for 48 hours, with a temporary interruption from 25d 18h to 26d 2h.

At first only a small disturbance followed a "sudden commencement" at 26d 19h 22m. A curious feature of this disturbance was its abrupt ending in a rapid fall of 45γ in N and 55γ in W, beginning at 27d 7h 35m. After an interval of about 6 hours disturbance was renewed and developed during the night of the 27th–28th into the greatest storm of the year, all components undergoing large and rapid fluctuations. Superposed on these fluctuations there is a well-marked oscillation of long period with maximum about 18h and minimum about midnight, and amplitude roughly 140γ in N, 120γ in W, and 190γ in V. Among the features of the disturbance may be noticed several very abrupt and sharp dips and peaks in N between 18 and 22h, accompanied by rapid changes in V which carried the trace beyond the limits of registration in both directions. The ranges recorded in the period under discussion were:—N, 1008γ; W, 663γ; V, 693γ. The N range is about half the H range recorded at the same time at Lerwick and about double that recorded at Stoneyhurst.[1] The disturbance died down at 28d 4h, after a rapid but irregular rise in all components, though there was minor activity until 19h.

[1] Nature, 123 (1929) p. 450.

No noticeable solar disturbance appears to have occurred during the month, but the first of the two considerable magnetic storms mentioned above occurred approximately one solar rotation period after one of the January sunspots.

March.—(Average Character Figure 0·94). During the first 10 days of the month there was continuous minor activity. A large "sudden commencement" at 11d 13h 53m marked the beginning of a considerable disturbance which lasted until the evening of the 13th and was presumably associated with a naked-eye sunspot in lat. 10°S, time of central meridian passage March 11·0d.[1] The fluctuations in the horizontal components were small but rapid until 12d 1h, when they increased in range, becoming very large during the next 6 hours; during this period there was a dip of some 450γ in V. From 7h till 14h V increased, reaching its maximum value for the storm at 13h 59m, after which it fell irregularly until about 13d 3h; N and W also increased until 12d 15h, afterwards falling until about midnight. The ranges recorded were:—N, 651γ; W, 399γ; V, 555γ.

Small movements in all components at 13d 22h were repeated very nearly 24 hours later. On the 15th–16th occurred a disturbance of which the most noticeable feature is the large oscillation of V, with maximum at 15d 17h and minimum at 16d 3h; the absolute maximum occurred in a sharp peak at 17h 8m, which is reproduced at Lerwick as a dip, although the general outline of the curve is of the same shape as at Eskdalemuir.

During the rest of the month there was no large disturbance, though no day was free from some slight agitation, the most considerable being from 20th to 22nd.

April.—(Average Character Figure 0·70). No large disturbance took place in April, though the three days 16th–18th were allotted character figure 2. A "sudden commencement" at 4d 9h 27m was followed by slight agitation until 19h, but no disturbance worthy of note developed. The period 9d 16h to 10d 11h was very quiet, but the usual minor activity was then renewed and continued till the end of the 13th. Another quiet period followed, but was broken at 15d 16h by the beginning of a moderate disturbance which lasted until the early hours of the 19th. The fluctuations of the horizontal components were irregular and present no very clear features for description. W was below its undisturbed value from 15d 21h to 16d 8h, except for two humps at about midnight and 4h. A rapid rise of 60γ in N, beginning at 0h 32m, was superposed on very small and rapid oscillations; N then fell irregularly to a minimum at 3h 40m which was followed by a rapid recovery. Very similar movements took place 22 hours later, beginning at 16d 22h 32m. During the night of the 15th–16th V rose gradually till 22h, afterwards falling slowly; a dip of 90γ occurred around 4h and was followed by a gradual rise until 18h, after which V fell slowly for about 4 hours. At 22h 32m, simultaneously with an abrupt rise in N and W, the fall in V became more rapid, resulting in a dip of some 70γ, with minimum at 17d 2h. During the 17th there was considerable agitation, which was continued in a smaller degree on the 18th. Conditions were very quiet from 19d 18h to 20d 23h and again from 22d 10h to 23d 12h. During the last three days of the month there was continued minor activity.

May.—(Average Character Figure 0·65). Continued agitation marked the first four days of the month until 4d 12h; conditions were then quiet for about 40 hours. Following a "sudden commencement" at 11d 23h 10m a small disturbance began about 13d 2h with irregular fluctuations in N and W and a dip in V; V rose during the morning and afternoon to a hump with rounded peaks at 15 and 18h, which were associated with jagged and irregular peaks in N. Disturbance was less during the next 24 hours. At 14d 21h an increased rate of fall of V synchronized with a sharp dip in W and a peak in N; the movements of N and W were superposed on the oscillations of very short period which are frequently found at about this time. There was slight disturbance throughout the 15th and 16th and until 17d 20h.

[1] Nature, 123 (1929), p. 425.

During the rest of the month there was continual minor activity. A small movement beginning at 23d 5h 30m consisted of a drop in N which reached a depth of 90γ at 6h 29m, and was followed by a partial recovery. The beginning of a small hump in W and a dip in V coincided approximately with the minimum in N. In the early hours of the 25th there were oscillations in N and W and a dip of about 60γ in V. A small disturbance took place on the 28th, beginning at 4h with small and rapid oscillations in N and W. N fell irregularly to a minimum at 13h, afterwards rising to a maximum shortly before 17h; there followed small fluctuations until 20h, when the disturbance died away. The movements of W were small; V fell gradually to a minimum at 14h and rose to a rounded maximum at 19h. The ranges were:—N, 156γ; W, 110γ; V, 55γ.

June.—(Average Character Figure 0·73). Minor activity marked the first nine days of the month, except for a quiet interval from 3d 22h to 6d 14h.

A moderate disturbance is regarded as beginning about 8d 2h, but little happened until the early hours of the 10th. Two small dips occurred in V at about 0h 30m and 2h, corresponding to small humps in W; after a gradual rise, another shallow dip occurred in V at 7h, slightly preceded by a dip of about 75γ in N, after which V continued to rise gradually to a rounded maximum at 18h. N rose slowly during the afternoon with many irregular fluctuations, reaching a maximum at about the same time as V; thereafter there were further fluctuations of the order of 60γ in range until 22h, when there was a temporary decrease of activity. At 11d 0h 35m N began to rise rapidly, reached a peak of 70γ at 0h 54m, and fell again somewhat less rapidly; this peak coincided with the lowest part of a dip in V.

During the next 24 hours the movements were of a similar character, but the afternoon maximum of N occurred about an hour earlier, while that of V took place shortly before 20h, simultaneously with a small dip in W and a peak in N. Disturbance was practically at an end at 12d 2h. The ranges were:—N, 196γ; W, 123γ; V, 110γ.

The next disturbance to be noted began about 21d 12h. The disturbance during this day and the next was small; the maximum of N occurred at 22d 20h 3m, after a rapid rise of 33γ, and was followed by a fall of 80γ in 25 minutes; simultaneously there was a very small hump in W and a dip in V. The 23rd was more disturbed, though the fluctuations were of small range. V rose during the afternoon in an irregular hump, falling again after 18h. The oscillations in N were small and rapid during the morning and afternoon; the interval from about 19 to 21h was rather less disturbed, but shortly after 21h very small and rapid oscillations in N and W were superposed on one or two larger oscillations; these ceased soon after 22h. V remained nearly constant from 23h to 3h of the 24th, when it began to fall, making a shallow dip and beginning to rise again at 5h. During the 24th there was continued agitation until 20h.

The ranges during the period just discussed were:—N, 161γ; W, 129γ; V, 65γ. About this time there were two naked eye-spots on the sun, in 9°S and 13°N lat. respectively, times of central meridian passage June 24·0d and June 24·5d.[1]

Conditions were very quiet from 25d 20h to 27d 8h, and again from 28d 21h to 29d 21h. During the afternoon of the 28th there was a slight increase of activity, during which V rose in a rather large hump of some 65γ. Somewhat similar conditions recurred on the 30th and were prolonged into the morning of July 1st.

[1] Nature, 124 (1929), p. 69.

July.—(Average Character Figure 0·90). There was a certain amount of activity during the first eight days of the month. A very small " sudden commencement " at 5d 9h 5m was followed by a minor disturbance during the next two days. The greatest activity occurred at about 5d 16h ; N and W rose to practically simultaneous maxima at 16h 30m, and immediately fell rapidly ; V rose to a rounded maximum soon after 17h and fell gradually until about 7h the next morning.

The 9th was quiet, but a large disturbance began in the early hours of the 10th. The oscillations were at first small and rapid and there were no large movements except a gradual fall in N from 6h to 10h ; but at 11h 35m there was a large " sudden commencement," after which the disturbance was much greater. Large peaks occurred in N at 12h 10m, 14h 34m, 16h 41m (the maximum for the storm), 18h 40m and 21h 29m. V rose to a maximum at 18h 35m, and fell irregularly to a minimum at 23h 10m. The minimum of N occurred 6 minutes earlier in a dip of very similar shape. Some agitation continued throughout the 11th, but conditions had become quiet by the early hours of the 12th. The ranges were :—N, 380γ ; W, 228γ ; V, 179γ. A large spot passed the sun's central meridian at July 10·7d in Lat. 6°S.[1]

Conditions remained quiet until the 14th. At 14d 16h 31m a " sudden commencement " marked the beginning of a disturbance which, though not particularly great, continued with about the same intensity until the end of the 16th, and in a smaller degree for a further two days. The most noteworthy movements were those of V, which were larger than usual in comparison with those of the horizontal components. The " sudden commencement " occurred during the normal afternoon rise of V ; the maximum was reached shortly before 20h and was followed by a fall which was slow for four hours but became very rapid at midnight. Between midnight and 15d 0h 40m V fell by 95γ, and it remained at a low value until about 4h 40m, when a gradual rise began, which lasted until 18h. N also fell rapidly during the 40 minutes following midnight, but recovered immediately and oscillated rapidly but irregularly until 7h. W was slightly below its undisturbed value from 14d 20h till 15d 3h. During the 15th V rose slowly to a maximum at 18h 14m and thereafter fell, slowly at first, but with increasing rapidity ; the fall became very rapid at 23h and the minimum value for the storm was reached at 23h 22m, and was followed by a rapid recovery. Between 23h and midnight there was a dip in N, with rapid oscillations, and a sharp rise and dip in W. During the morning of the 16th conditions were quiet, apart from small rapid oscillations. During the afternoon V rose in a large rounded hump, the maximum for the storm occurring at 16h 19m ; it then fell, irregularly at first, then very slowly until 17d 2h. N and W rose to maxima soon after 15h and continued to oscillate irregularly until nearly 23h. During the rest of the 17th minor fluctuations occurred continually, and these gradually died away during the 18th. The ranges during the period July 14–17, were :—N, 272γ ; W, 226γ ; V, 309γ. A sunspot passed the central meridian at July 17·1d.

The 19th was quiet, but there was some activity on the 21st, 22nd and 23rd, and also on the afternoon of the 24th, and in a minor degree on most days till the end of the month ; the period 27d 20h to 29d 14h was comparatively quiet.

August.—(Average Character Figure 0·71). A " sudden commencement " at July 31d 21h 6m was followed by a small dip in V between midnight and August 1d 4h, and small and rapid oscillations in N and W during the night and early morning. The records for the next two days are defective and no account can be given of the storm ; judging, however, from Lerwick, it was of moderate intensity.

[1] Nature, 124 (1929), p. 631.

There was activity of a minor character on the 4th–5th and the 12th. On the 14th a " sudden commencement " at 12h 27m marked the beginning of a considerable disturbance. The oscillations in W, though rapid, were smaller than usual in comparison with the other components. In N and V the main features are normal, consisting of maxima during the afternoon, followed by rapid but very irregular falls ; sharp dips took place in both shortly before 22h and between midnight and 15d 1h. After this the oscillations were small and very rapid for nearly 24 hours, and then more or less died away.

A small storm occurred at Abinger beginning at 14d 16h, and the following night aurora was seen from Sidmouth.

Activity was renewed on the 16th and the 18th and 19th. On the 18th V was below its undisturbed value from 0h to 8h, while continuous minor fluctuations took place in N and W ; shortly after 10h there was a dip about 75γ in N.

During the rest of the month conditions were quiet.

September.—(Average Character Figure 0·80). There was no very large storm this month, but a number of minor disturbances.

A small disturbance occurred on the 7th, after a " sudden commencement " at 6d 23h 30m. The movements in N and W consisted of small rapid oscillations superposed on irregular fluctuations of longer period. V was below its undisturbed value from the " sudden commencement " till 7d 8h, and rose during the afternoon in a rounded hump with maximum about 18h.

There was a " sudden commencement " at 9d 21h 30m. The initial movements were less sudden than usual, and in addition oscillations of very small amplitude and period occurred simultaneously, and for some 20 minutes both before and after. This seems to be another example of the very small oscillations which are frequently found for about half an hour between 20h and midnight. In this case other groups of oscillations occurred at about 14h and 18h and the 4-hour period seems to be something real, as there was increased activity again around 2h and 6h on the 10th. The maximum of N occurred in a small peak shortly before 18h, and there was another peak two hours later ; these coincided with small peaks in V and dips in W.

Great activity continued during the 11th and for the next five days. This was particularly marked on the evening of the 14th, when oscillations with a range of about 120γ took place in N between 16 and 17h and between 19h 30m and 20h 30m.

A small disturbance began soon after noon on the 21st and continued till the end of the 22nd. At 21d 21h 5m a rapid drop of 75γ took place in W, and soon afterwards a small hump in N ; a series of very small and rapid oscillations occurred simultaneously in both components. About half an hour after midnight similar movements, but of the opposite signs, began, and these were associated with a rapid drop of some 80γ in V. V remained at a low value for the next 6 or 7 hours. N dipped at 22d 11h, and continued to fluctuate irregularly until 22h. At 16h 26m a drop took place in W similar to the one on the previous evening.

Activity continued during the succeeding days until the end of the 27th. Shortly before 27d 20h there was a rapid rise of 105γ in N, accompanied by very rapid oscillations ; there was also a small oscillation in W and a drop in V. The remainder of the month was quiet.

October.—(Average Character Figure 0·84). During the first six days there was almost continuous activity of a low order. A sunspot in lat. 11°N passed the central meridian at 4·7d[1] but there was no particular disturbance around this time, although between 14h and 24h on this day there were several groups of small and rapid oscillations in N and W.

The first disturbance to be noted began on the 7th, with a drop of 70γ in N between 9h 40m and 10h 20m. Fluctuations in all components were rapid but not very large during the next 48 hours or more. Perhaps the most noticeable feature is the gradual drop in W from 16h to 23h on the 7th, followed by a rise of 125γ between 21h 50m and 22h 10m ; simultaneous with the latter was a drop of 78γ in V. On the 8th there was a slight dip in N between 11 and 13h, the minimum for the storm occurring in a sharp dip at 11h 53m. Abrupt peaks occurred in N at 17h 40m, 20h 34m and 23h 0m ; each of these coincided with a small drop in V and an oscillation in W. The disturbance continued on the 9th, but the only movements worthy of note were sharp rises of about 70γ in N at 14h 24m, 18h 57m and 21h 40m, associated with small movements in W and V. The ranges during the 7th–9th were :—N, 253γ ; W, 202γ ; V, 173γ.

Sunspots were visible in lat. 19°S from October 6th to 17th (central meridian passage 10·8d) and in lat. 10°S from the 7th to 19th (central meridian passage 13·4d).[2]

None of the succeeding days was free from minor activity, and on the 16th a considerable disturbance began with a " sudden commencement " at 11h 13m. Many large and rapid fluctuations took place in all components between 16d 15h and 17d 3h. V increased rapidly after 16d 15h. From 17h to 21h was a period of great activity. The maximum for the storm of N and V, and a sharp though small peak in W, occurred at 18h 7m, and all three components fell abruptly shortly afterwards. At 20h 36m N and V began to fall abruptly ; V had fallen by 220γ to a sharp minimum at 20h 56m ; and N by 260γ a minute or two later, recovering immediately. Thereafter the fluctuations were less rapid but still irregular till 17d 3h. There was a small outbreak of activity from about 7–8h, but apart from that oscillations were small on the 17th until at 16h 17m an abrupt movement, similar in all components to the " sudden commencement " of the day before, marked a renewal of disturbance, in which the sequence of events also was somewhat similar. The disturbance died away during the early hours of the 18th. The ranges were :—N, 365γ ; W, 331γ ; V, 383γ.

It is perhaps worth mentioning that there is a close similarity between the curves for 17d 22h to 18d 8h and those for 18d 22h to 19d 8h, especially in the case of N. A tall peak in N soon after 17d 22h, and dips at 18d 1h 30m and 5h, were reproduced very closely 24 hours later.

From the end of the 25th till noon of the 28th conditions were quiet. During the next 48 hours small oscillations, with period of the order of 100 secs. and amplitude 1 or 2γ in N, are particularly noticeable. During the 30th a disturbance of moderate intensity developed, beginning with a small dip in N between 15 and 17h. Outbursts of activity between 19 and 20h, about 22h and between 31d 1 and 2h, resulted in considerable oscillations in all components.

A sunspot, visible from October 24th till November 6th in lat. 10°N, passed the central meridian at October 31·0d.[3]

November.—(Average Character Figure 0·67). Conditions were disturbed during the first seven days of the month, particularly from 2d 20h to the morning of the 4th, during which period ranges of 342, 251 and 206γ were recorded in N, W and V.

[1] Nature, Vol. 124, p. 631. [2] Nature, Vol. 124, p. 631. [3] Nature, Vol. 124, p. 737.

N was below its undisturbed value from 5 to 13h on the 3rd. During the afternoon three peaks occurred in N and V, and three dips in W; in each case the maximum in V occurred first, followed after a minute or two by the minimum in W, with the maximum in N a few minutes later still; the maxima in N occurred at 15h 25m, 17h 14m and 19h 22m.

A sunspot in lat. 14°N passed the central meridian at 3·7d. Another in lat. 10°S passed the central meridian at 9·6d,[1] but there was little disturbance at this time, the 8th to 14th inclusive being quiet. This sunspot had a metallic prominence, and was a return of that which passed the central meridian at October 10·8d.

A small disturbance began in the early morning of the 16th, and continued during the day, dying away rapidly after 22h. The periods of greatest activity were from 14h 30m to 16h, and from 18h to 21h. In each case there was a peak in V and irregular oscillations in N and W.

Conditions were then quiet, with the exception of the afternoon of the 20th, until the 26th. During the remainder of the month there was continued activity of a low order.

A sunspot, which was a new outbreak in the place of that of October 31·0d, passed the central meridian at November 27·9d in lat. 13°N, and a conspicuous naked-eye spot, a return of that of November 3·7d, at November 30·3d in lat. 16°N.[2]

December.—(Average Character Figure 0·84). A disturbance began shortly before noon on the 3rd and lasted until the morning of the 7th, during which time the ranges were 161γ in N, 114γ in W and 201γ in V. The movements in the horizontal components were irregular and without any remarkable features. V was below its normal value during the early hours of the 4th, 5th and 6th, rising to irregular humps during the afternoons. After a few irregular oscillations in N and W between 20 and 21h on the 6th, the disturbance died away.

A small disturbance, with ranges of 110γ in N, 141γ in W and 114γ in V, occurred between the 9th and 12th. For the most part this took the form of activity of a small order, but there were considerable movements in W and V during the afternoon of the 11th and the morning of the 12th; a dip occurred in W between 21 and 23h on the 11th and in V between 0 and 2h and between 4 and 6h on the 12th, the two last having appeared on a smaller scale 23 hours earlier.

Conditions were quiet from 12d 16h to 16d 10h. At 16d 11h 34m a very small "sudden commencement" marked the beginning of a disturbance which, judged by the ranges, was among the half-dozen largest of the year. The main period of activity was, however, the three hours from 17 to 20h on the 16th, and it seems significant that one of the largest sunspots of the year passed the central meridian in lat. 6°N at 16·5d, and a smaller one in lat. 3°S at 16·7d. Between 18h and 18h 45m the maximum and minimum of both N and W, and the maximum of V, for the storm, occurred; but although before 17h and after 20h the oscillations in N and W were mostly small, V was rising rapidly from 12h onwards, and continued to fall until midnight. There was a renewal of disturbance, but on a smaller scale, the following night.

A moderate disturbance began at the end of the 21st and continued for about 48 hours. V rose in an irregular hump on the afternoon of the 22nd, and fell from 20h till midnight, during which period there were considerable oscillations in N and W. Activity continued till the end of the 23rd, and in fact for several days afterwards, no day during the rest of the year being free from some small disturbance.

A very large naked-eye sunspot crossed the central meridian in lat. 16°N at 27·5d. This spot occupied the place of that of November 30·3d.

Station Level

NOTE.—When pressure exceeds 1000 mb. the leading figure 1 is not printed, *i.e.*, 1005·6 mb. is written 005·6. This rule does not, however, apply to monthly means.

Readings in millibars at exact hours, Greenwich Mean Time.

169. Eskdalemuir : H_b (height of barometer cistern above M.S.L.) = 237·3 metres. **March, 1929.**

NOTE.—The initial 2 or 3 of the readings is omitted, *i.e.*, 275·0 degrees absolute is printed 75·0.

TEMPERATURE: ANNUAL MEANS OF HOURLY VALUES.

From readings in degrees absolute at exact hours, Greenwich Mean Time.

194. Eskdalemuir: Louvred Hut: $h_t = 0{\cdot}9$ metres. **1929.**

† The totals and durations for individual months are printed in the tables on the following pages.

NOTES ON RAINFALL.

212. Eskdalemuir. **1929.**

Rainfall Duration.—There were 146 days on which no duration of rainfall was registered. There were 42 days on which the duration of rainfall was registered as 0·1 hour to 1·0 hour, 22 days with 1·1 to 2·0 hours, 68 days with 2·1 to 6·0 hours, 61 days with 6·1 to 12·0 hours, and 26 days with more than 12 hours. The day with the greatest duration was July 10th, when the duration was 22·6 hours, the amount falling being 40·3 mm. On January 29th, the duration was 22·3 hours and the amount falling 18·1 mm.

Notable Falls of the Year.

(*a*) The greatest amount in a 60-minute period was 18·1 mm., which was recorded between 14 h and 15 h, July 5th. On this day 5 mm. of rain fell in 6 minutes. Falls of 5 mm. in less than one hour occurred on 18 days.

(*b*) Details of the greatest continuous falls are as follows :—

Date	Amount. mm.	Duration. hrs.
July 9th—10th	27	21·2
August 3rd	33	14·2
October 1st	28	8·7
October 23rd—24th	32	15·0
November 4th—5th	45	15·3
November 11th	46	12·3
December 2nd	29	8·3
December 20th—21st	29	12·5
December 28th—29th	30	13·8

Wet Periods.

(*a*) There was one "rain spell" (i.e., a period of fifteen or more consecutive days on each of which 0·2 mm. or more of rain fell), viz., November 23rd to December 15th.

(*b*) There were no "wet spells" (i.e., periods of fifteen or more consecutive days on each of which 1·0 mm. or more of rain fell). The period November 23rd to December 14th failed to classify as a "wet spell" in having only 0·3 mm. on December 1st.

Dry Periods.

(*a*) There was one period of "absolute drought" (i.e., fifteen or more consecutive days on which less than 0·2 mm. of rain fell), viz., February 26th to March 20th.

(*b*) There was no period of "partial drought" (i.e., twenty-nine or more consecutive days, the mean rainfall of which did not exceed 0·2 mm. per day).

Amounts in millimetres, for periods of sixty minutes, between the exact hours, Greenwich Mean Time.

213. Eskdalemuir : H_r (height of receiving surface above M.S.L.)= H (height of station above M.S.L.)+ h_r (height of receiving surface above ground) = **242·0** metres + **0·4** metres. **January, 1929.**

Direction expressed in degrees from North (E = 90°, S = 180°, W = 270°, N = 360°). Speed in metres per second.

241. Eskdalemuir : H_a (height of anemograph above M.S.L.) = Height of ground above

* Defective Record. † Mean for 29 days only : 20th omitted.

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 235 metres + 15 metres. **November, 1929.**

NOTE.—The Potential Gradient is reckoned as positive if the potential increases upwards. For indeterminate potential gradient the following notation is used ; z+, Indeterminate, positive value ; z−, Indeterminate, negative value ; z±, Indeterminate in magnitude and sign.
(*a*) Mean of all positive readings. (*b*) Mean from all complete days using both positive and negative readings.

Mean Values for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

The Potential Gradient is reckoned as positive if the potential increases upwards. For indeterminate potential gradient the following notation is used: z+, Indeterminate, positive value ; z, −Indeterminate, negative value ; z±, Indeterminate in magnitude and sign.

(*a*) Mean of all positive readings. (*b*) Mean from all complete days using both positive and negative readings.

The departures from the mean of the day are adjusted for non-cyclic change.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 322–333. § For explanation *see* p. 169.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

Q denotes an " International Quiet Day," while D denotes a disturbed day used for the computation of Tables 322–333.

TERRESTRIAL MAGNETIC FORCE: VERTICAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

279. Eskdalemuir. (Z.) 44,000 γ (·44 C.G.S. unit) + **March, 1929.**

Q denotes an " International Quiet Day," while D denotes a disturbed day used for the computation of Tables 322–333.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

283. Eskdalemuir. (Z.) 44,000 γ (·44 C.G.S. unit) + **April, 1929.**

* Light failed. † Mean of 27 days; 1st, 2nd, 3rd and 5th omitted.

§ For explanation *see* page 169. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 323–334.

TERRESTRIAL MAGNETIC FORCE: NORTH COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

301. Eskdalemuir. (X.) 15,000 γ (·15 C.G.S. unit) + **September, 1929.**

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 323–334.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

311. Eskdalemuir. (Z.) 44,000 γ ('44 C.G.S. unit) + **November, 1929.**

Q denotes an " International Quiet Day," while D denotes a disturbed day used for the computation of Tables 323–334.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

315. Eskdalemuir. (Z.) 44,000 γ ('44 C.G.S. unit) + **December, 1929.**

§ For explanation *see* page 169. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 323–334.

(Not corrected for the effect of the North Force on the West Magnetograph, or *vice versa*, or for the effect of the Horizontal Force on the V.F. Balance).

Departures from the mean of the day adjusted for non-cyclic change.

NORTH COMPONENT (*all days except Aug.* 1, 2, 3 *and* 10).

DIURNAL INEQUALITIES OF THE MAGNETIC COMPONENTS, DECLINATION, INCLINATION, AND HORIZONTAL FORCE.—INTERNATIONAL QUIET DAYS.

Departures from mean of the day adjusted for non-cyclic change.

DECLINATION (measured positive towards the West) (*Quiet Days*).

DIURNAL INEQUALITIES OF THE MAGNETIC COMPONENTS, DECLINATION, INCLINATION AND HORIZONTAL FORCE.—SELECTED DISTURBED DAYS.

Departures from mean of the day adjusted for non-cyclic change.

DECLINATION (measured positive towards the West) (*DisturbedDays*).

NOTES.—*Results derived from absolute observations only. † A local anomaly is known to exist at the site of the Observatory.

Sitka.—A change of magnetometer was made in 1929 which affected declination observations. The systematic difference is —1′·2 E.

Potsdam.—Magnetic Observation at Potsdam Observatory ceased after the middle of 1928 on account of electrification of Berlin railways.

Abinger.—The values of Inclination and Vertical Force for 1929 depend upon direct measurement of the vertical component of the earth's field with a coil-magnetometer. The change of method involves a discontinuity in the observed secular change of mean values of these elements.

San Juan, Porto Rico.—The results for 1927 are from the months January to May only.

Batavia (Kuyper), Java.—Observations in 1927 were made at Buitenzorg Lat. 6° 11′ S., Long. 106° 49′ E.

Apia, Samoa.—The results for 1928 are for five months only. For 1929 the results in Inclination and Vertical Force are for six months only.

La Quiaca, Argentina.—Results for 1928 are from hourly values January–April, combined with absolute observations May–December.

INTRODUCTION.

SITE.

Valentia Observatory derives its name from the fact that it was originally established on Valentia Island in 1867. It was removed to the mainland in March, 1892, and now lies in a direct line between the old site on Valentia Island and the town of Cahirciveen, about 2½ miles (4 km.) north-east from the former, and three-quarters of a mile (1 km.) south-west of the latter. It is quite remote from any other buildings. The general character of the country surrounding the Observatory is hilly. The eastern bank of the Cahir river is about 150 metres to the westward, and in that direction there is no very high ground between the Observatory and the open sea, some 3½ miles (6 km.) away. To the north-west, however, are hills varying in height from 400 (120 m.) to 900 feet (275 m.), the highest being less than 3 miles (5 km.) distant. These are only separated by a narrow gully running in a N N W direction from other hills equally high, which stretch away to the northward: the nearest of these is but little more than a mile (1½ km.) from the Observatory. Beyond the town of Cahirciveen to the north-east the river opens out considerably, and the country in this direction becomes an open boggy basin, rising by only a gentle gradient. Southward of this, however, it soon rises again, and at about a mile south-east of the Observatory it culminates in the hill Bentee upwards of 1,245 feet (380 m.) in height. Still further south it opens out once more to a distance of nearly 5 miles (8 km.) from the Observatory, where there is a range of hills running east and west, and varying in height from 400 (120 m.) to 1,300 feet (400 m.). To the south-west there is an opening to the sea, between Valentia Island and the mainland; and the circle of hills is completed by those on the island itself, the highest of which is about 800 feet (240 m.) high, and bears about west-south-west from the Observatory. Photographs of the Observatory building, together with a site plan, showing the disposition of the various instruments were reproduced in the introduction to the 1928 volume.

METEOROLOGY.

The elements dealt with in the following tables are: atmospheric pressure, air temperature, humidity, rainfall, sunshine, wind speed and direction, minimum temperature on the grass, together with a diary of cloud visibility and weather.

Pressure and Temperature.—The photographic barograph and thermograph are installed in a room on the ground floor of the Observatory tower. The standard Fortin barometer, from which the control readings at 9h, 15h and 21h are taken, is mounted in the same room beside a window which faces the north-east. The stems of the dry and wet bulb thermometers pass out into the screen placed against the north wall of the tower. Close to the bulbs of these thermometers are the bulbs of the standard thermometers from which the control readings at 9h, 15h and 21h are taken.

Rainfall.—The Beckley raingauge and the 8-inch (20·3 cm.) check gauge are placed in a railed-off enclosure about 40 metres to the north of the tower.

Sunshine.—The recorder is cemented to a wooden rail on the roof of the tower. The exposure of the sunshine recorder is such that there is no appreciable loss of record due to obstructions in the months of May, June, July and August. During the remainder of the year the hill Bentee lying to the south-east cuts off early morning sunshine. The reduction in possible record, assuming that the recorder becomes sensitive to sunshine only when the sun is at an altitude of more than three degrees, is shown in the following table for the 1st and 15th of each month :—

Reduction in Possible Record in Tenths of an Hour.

Month.	Jan.	Feb.	Mar.	Apr.	Sept.	Oct.	Nov.	Dec.
1st.	·5	·5	·7	·5	·3	·7	·5	·6
15th.	·6	·5	·7	·3	·5	·7	·5	·5

Wind, Speed and Direction.—Up to 1925 the measurements of Wind Speed and Direction as given in Tables 413-424, were obtained from the Robinson Cup Anemograph on the roof of the Observatory tower. Commencing with the 1926 values, measurements of Wind Speed and Direction published in the Observatories' Year Book are taken from the records of the Dines Pressure-tube Anemograph. This instrument stands in an open field, about 250 metres S E by E of the Observatory tower. The field slopes northwards and downwards to the river Cahir. About 1 mile (1½ km.) to the south-east is the highest point (1,245 feet) of the hill Bentee which extends for some little distance in a northerly and south-westerly direction. A description of the surrounding country has already been given.

In a few instances where records of the Pressure-tube Anemograph have been defective, the required values have been obtained from the records of the Cup Anemograph, a suitable adjustment of such values having been made in accordance with the table in the General Introduction showing the effect of exposure on the two instruments. Values thus obtained are entered as interpolated values.

Minimum Temperature on the Grass.—The grass minimum thermometer is of the type described in the General Introduction. It is exposed over short grass in the field enclosure. It is set at 18h and read at 7h on the succeeding day, the observation being entered to the day of reading.

Visibility.—Lists of the objects used for visibility observations and their distances and bearings from the point of observation are given in the following tables.

LANDWARDS VISIBILITY OBJECTS AT VALENTIA OBSERVATORY.

Indication letter of object.	Standard distance of object.	Actual distance of object.	Bearing of object in degrees from N.	Description of object.
	Metres.	Metres.		
A	25	25	350°	Gate near workshop.
B	50	50	345°	North fence of enclosure.
C	100	100	125°	Hedge at S. end of vegetable garden.
D	200	200	330°	Notice board on beach.
E	500	500	360°	Hulk on shore.
F	1,000	1,100	50°	Parsonage.
G	2,000	1,910	55°	Wireless school
Intermediate object	—	3,500	20°	Top of Castlequin Mountain.
h	4,000	—	—	No object available. (Top of Castlequin well visible.)
I	7,000	7,600	40°	Top of Knocknadober Mountain.
J	10,000	10,000	220°	Kilkeaveragh Mountain.
Intermediate object	—	17,000	55°	Drung Hill.
k	20,000	—	—	No object available. (Drung Hill well visible.)
l	30,000	—	—	No object available.
m	50,000	—	—	No object available.

SEAWARDS VISIBILITY OBJECTS AT VALENTIA OBSERVATORY.

Indication letter of object.	Standard distance of object.	Actual distance of object.	Bearing of object in degrees from N.	Description of object.
	Metres.	Metres.		
F	1,000	1,000	205°	Farmhouse on skyline.

I	7,000	6,500	250°	Ridge between two hills on Valentia.
J	10,000	10,000	220°	Kilkeaveragh mountain.
k	20,000	—	—	No object available.
Intermediate objects	— —	23,500 25,500	320° 325°	Mount Eagle. Croaghmarhin Mountain.
l	30,000	—	—	No object available. (Croaghmarhin well visible.)
m	50,000	—	—	No object available. (Croaghmarhin exceptionally visible.)

Two observations, one in a landwards direction, the other in a seawards direction, are made at each hour of observation. The position of the Observatory is such that a distinction between visibility landwards and seawards cannot be made when the range of visibility is less than 1,000 yards. Objects corresponding with the letters A to E have therefore been included in the table of landwards objects only. Kilkeaveragh Mountain is used as both a landwards and seawards object corresponding with J.

Entries of "l" and "m" for visibility in a landwards direction are made :—

(*a*) When Croaghmarhin Mountain (see table of seawards objects) is clearly visible and there is reason to believe that the range of visibility in a landwards direction is as good as, or nearly as good as, visibility seawards.

(*b*) When Croaghmarhin Mountain is invisible but there is reason to believe from the appearance of Drung Hill that the range of visibility landwards is greater than the range seawards and is sufficiently good to justify the entry made.

When the mountains used as objects at 3,500 metres and beyond are cloud capped the appropriate entries for the range of visibility are determined by the clearness or otherwise with which the lower parts of the mountains can be seen.

There is a complete absence of industrial activity within a radius of about a hundred miles from the Observatory ; the observations are therefore not much affected by smoke pollution of the atmosphere.

Notes on the Meteorological Summaries.

The Weather of 1929.—An outstanding feature of the year was the persistence of rain and high winds in December. No less than 292 millimetres fell during this month and there were only two days on which no rain was measured. Wind reached or exceeded force 6 on the Beaufort scale on 22 days and gales were experienced on 6 days.

Another feature of the year was the unusually fine weather for the time of year experienced in March : sunshine was 59 per cent. and temperature 1·6a (2·9°F.) in excess of normal : there were only 5 days in the month with measurable rainfall.

Pressure.—No change in the values used for reducing pressure at station level to pressure at mean sea level was made at Valentia Observatory by the introduction in 1928 of the revised scheme as set out in the General Introduction.

The mean pressure for the year was approximately normal. Of the monthly mean pressures seven were higher and five lower than normal. The departures ranged from an excess of about eleven millibars in March to a deficiency of twelve millibars in November.

Details of the Fourier analysis of the diurnal inequalities of pressure for the year are given in Table A. For the year considered as a whole the amplitude of the 24-hour term is less than for the period 1871–1915 ; the arithmetic mean for the twelve months is considerably higher than that of the period, which points apparently to an abnormal amount of variation in the 24-hour term phase angles throughout the year. The normal monthly phase angles for the 24-hour term vary between 203° and 149°. In 1929 there were only two months (July and August) with phase angles within this range : wide deviations from normal are shown in most of the remaining months.

For the year considered as a whole the amplitude of the 12-hour term is lower than average. For the seasons the amplitude of the 12-hour term is lower than normal in winter and summer : at the equinoxes the amplitude is normal. For the individual months with the exception of November which is markedly low 12-hour phase angles do not show very marked departures from normal.

There are no very remarkable deviations from normal in the amplitudes of the 8-hour and 6-hour terms. The phase of the 8-hour term has a seasonal variation, changing somewhat rapidly at the equinoxes by approximately two right angles, which is normal.

Temperature.—The mean temperature for the year 1929 was 0·18a (0·32° F.) above normal. For the individual months mean temperatures did not differ greatly from normal. March, with an excess of 1·63a (2·93° F.) showed the greatest departure.

The harmonic analysis of the monthly and seasonal diurnal inequalities of temperature is given in Table B. For the year considered as a whole the amplitude of the 24-hour term is normal. The highest of the seasonal amplitudes for the 24-hour term is found in summer, as is usual. The amplitude at equinox is above normal, and the winter and summer amplitudes below normal. The seasonal variations in phase angle of the 24-hour term are normal. Of the individual monthly values March is remarkably high being the highest of any month in the year, whereas normally each of the six months April to September is higher.

For the 12-hour term the amplitude is low for the year considered as a whole; the seasonal values follow the normal sequence in amplitude, but the values at all seasons except equinox are low. Of the individual monthly values January and March are remarkably high. Phase angles for equinox and winter are normal, the summer value is rather high.

There is nothing very noteworthy as compared with normal in the 8-hour and 6-hour amplitudes and phase angles. The amplitudes for March in both terms are decidedly high. The approximate opposition in phase as between winter and summer in the 8-hour term is normal.

Rainfall.—The total rainfall for the year was 8 per cent. above normal, the actual excess being 115 millimetres. The month with the highest rainfall was December, with 292 millimetres, this amount being 73 per cent. more than normal. The lowest monthly total was that for March, the 34 millimetres which fell during that month being only 30 per cent. of the normal amount.

Bright Sunshine.—The total amount of bright sunshine for the year 1929 was about 3 per cent. less than the normal. Five months had more than average sunshine, the greatest excess being about 59 per cent. for March. The most notable deficiency was for October, the total sunshine for this month being 67 per cent. of normal.

Cloud and Weather.—The mean amount of cloud at all observation hours was 7·2. The most cloudy month was October, with a mean cloud amount of 8·0. The month with least cloud was March with a mean of 5·0.

Visibility.—The observations of visibility in tables 428–439 refer to visibility in a landwards direction. The observations, when the range of visibility seawards differs from the range landwards, are shown in the following table :—

NOTE.—The seasonal means are derived from the following grouping of months:—*Winter:* January, February, November and December; *Equinox:* March, April, September and October; *Summer:* May to August, inclusive.

TERRESTRIAL MAGNETISM.

Notes on the Magnetic Observations for the year 1929.

Absolute observations of declination, horizontal force and inclination were made weekly at the Valentia Observatory during the year 1929. The instruments in use were the same as in previous years, namely, the Dover unifilar, No. 139, with collimator magnet 139A and mirror magnet 139C, and the Dover dip circle, No. 118. The mean times of observation were 10·21 for the declination, 11·44 for the horizontal force and 14·30 for the inclination, all according to Greenwich Mean Time. In the individual observations the greatest departure from the mean time in any element was 3 minutes. The deflection of the mirror magnet was measured for two distances of the collimator magnet, namely, 30cm. and 40cm. The complete deflection observation consisted of eight readings of the mirror magnet. The distribution constant, P, used for 1929 was computed from the mean deflections for 30cm. and 40cm. for the seven years 1922–1928 inclusive. The mean P so obtained was 7·63. The moment of the collimator magnet has decreased at the rate of about 1 unit per annum.

The values of the declination, horizontal force and inclination obtained in the absolute observations are given in detail in Table C. All the observations made are included in this table, but in Table D the mean monthly values are computed from only such of the absolute observations as were taken at times subsequently found, by reference to the Eskdalemuir magnetograph curves, to be free from serious disturbance. Observations in Table C taken at disturbed times, and not, therefore, utilised for the mean values in Table D, are marked with an asterisk. The north, west and vertical components and the total force for each month and the year are computed from the corresponding mean values of the observed elements.

Westerly declination has diminished by 10′·7 as compared with 1928. From 1927 to 1928 the decrease was 11′·5 and in the previous 12 months 11′·3. The average annual decrease for the five years 1920–1925 was 11′·1, for the five years 1915–1920 it was 9′·2, and for the five years 1910–1915 it was 8′·2. During the five years ending in 1929 the average annual decrement is 11′·5 so that the rate of the eastward movement of the magnetic needle appears to have increased slowly.

Northerly inclination increased 0′·3 from 1928 to 1929. The corresponding change for the preceding year was +0′·1, and for the year previous to that −0′·9. From 1910 to 1915 the average yearly decrease was 1′·0, from 1915 to 1920 0′·5, and from 1920 to 1925 1′·1. For the five years 1924–1929 the average change per year is −0′·2. Inclination, therefore, is apparently diminishing at a slow rate, but the change in the opposite direction for the past two years makes it uncertain whether the decrease will be maintained.

Up to 1920 the mean annual values of horizontal force had shown a steady decline from year to year. In the years 1921 to 1924 and in 1927 the change was in the opposite direction, each year having a mean value higher than that of the preceding year. It would appear that the increase was temporary since a decline was in evidence from 1924 to 1926 and again from 1927 to 1929. The amount of annual change is shown in the following table :—

Period.	Annual Change.
1910–15	5γ decrease (mean value).
1915–20	6γ ,, (mean value).
1920–21	8γ increase.
1921–22	1γ ,,
1922–23	3γ ,,
1923–24	2γ ,,
1924–25	5γ decrease.
1925–26	14γ ,,
1926–27	2γ increase.
1927–28	11γ decrease.
1928–29	5γ ,,

The reversal of the annual change in the horizontal force from 1920 to 1924 and from 1926 to 1927 was not accompanied by any such reversal in the total force. From 1910 to 1915 the average yearly change in the total force was -49γ, from 1915 to 1920 it was -33γ and from 1920 to 1925 it was -32γ. From 1924 to 1929 the mean annual change is -25γ, so that the total force has continued to decrease, but at a rate which is apparently diminishing gradually. The individual changes from year to year as shown in Table D are somewhat irregular, but this may be due in considerable measure to instrumental uncertainties. The total force is computed from the horizontal force and the inclination, using the formula $T = H \sec. I$, so that an error of $0'{\cdot}1$ in I would give an error approximately 4γ in T at Valentia. In addition, it is to be remembered that the secular change data for Valentia are obtained from absolute observations made at fixed hours at any of which the value obtained for an element may differ, by an amount which is not necessarily constant, from its true mean value for the day of observation. It is by no means improbable that owing to this and errors of observation, uncertainties to the extent of several tenths of a minute of arc may be introduced into the mean value of I for the year. For the average change over a series of years these possible errors are naturally much diminished and the average fall of 35γ per annum in the total force obtained from the values in Table D is probably a close approximation to the true change. This continued decrease in the total force indicates that the rise in the value of the horizontal force observed from 1920 to 1924 and from 1926 to 1927 was not a true increase in the magnetic field but merely a component increase arising from the fall in the inclination, which becomes proportionally more effective in the horizontal component as the actual inclination angle itself becomes smaller. The magnetic field in the Valentia district continues to become less year by year, therefore, although without observations of inclination the opposite would have appeared to be the case in some recent years.

NOTE.—When pressure exceeds 1000 mb. the leading figure 1 is not printed, *i.e.*, 1005·6 mb. is written 005·6. This rule does not, however, apply to monthly means.

Readings in degrees absolute at exact hours, Greenwich Mean Time.

358. Cahirciveen (Valentia Observatory) : North Wall Screen : h_t (height of thermometer bulbs above ground) = 1·3 metres.

January, 1929.

388. Cahirciveen (Valentia Observatory). NOTES ON RAINFALL. **1929.**

Notable Falls of the Year.—

Details of the greatest continuous falls are as follows:—

Amount.	Date.	Time.
mm.		
39·2	November 10 to 11	23 h 40 m — 20 h 30 m
37·3	July 27 to 28	14 h 30 m — 13 h 5 m
30·6	December 1 to 2	19 h 5 m — 5 h 0 m
28·9	November 18	6 h 35 m — 16 h 20 m
18·0	October 1	10 h 30 m — 15 h 0 m

The highest fall of the year between one exact hour and the next was 7·7 mm. between 19 h and 20 h on November 9th; the period occupied by this fall was, however, only 35 minutes, it being part of a fall of 13·3 mm. which commenced at 18 h 0 m and ceased at 19 h 35 m.

Dry Periods.—

There was a period of 20 days, from February 28th to March 19th, during which no rain fell: with one exception (20 days in 1925) this is the longest dry period since 1921.

Wet Periods.—

Between November 1st and December 31st (61 days) there were only three days (Nov. 17th, Dec. 15th and Dec. 16th) without rain. Between November 18th and December 14th (27 days) there was rain every day and on only two days was the fall less than 2·0 mm.

Amounts in millimetres, for periods of sixty minutes between the exact hours, Greenwich Mean Time.

389. Cahirciveen (Valentia Observatory) : H_r (height of receiving surface above M.S.L.)=H (height of station above M.S.L.)+h_r (height of receiving surface above ground)=9·1 metres+0·5 metre. **January, 1929.**

Hour. G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 17 metres + 13 metres.

January, 1929.

Hour. G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = **17** metres + **13** metres.

March, 1929.

Hour. G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 17 metres + 13 metres.

July, 1929.

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 17 metres + 13 metres. **November, 1929.**

NOTES :—(1) The initial 2 of the readings is omitted, *i.e.*, 275·0 degrees absolute is written 75·0.
(2) The minimum refers to the interval from 18h. the previous day to 7h. on the day to which it is entered.
(3) Annual Mean 278·9.

428. Cahirciveen (Valentia Observatory). January, 1929.

Beckley Raingauge Rim	0·53

INTRODUCTION.

The Observatory was built in 1769 as the private observatory of King George III. Since 1842 it has been devoted to physics and meteorology. The meteorological records are continuous from 1854. The Observatory is in the Old Deer Park Richmond (Surrey), about 10 miles (16 km.) to the west of the City of London. The Observatory stands on a low artificial mound whose level is about 1½ metres higher than that of the surrounding park. Round the Observatory a golf course has been laid out. The river Thames is distant about 300 metres on the north and west. Kew Gardens, which are extensively wooded, lie to the east-north-east, the nearest point of the Gardens being about 600 metres away. The town of Richmond, to the south-east, is about 1,100 metres distant. On the east side of the Park is the main road from Richmond to Kew; on the south side the railway from Richmond to Twickenham. An open area partly wooded, Syon Park, lies to the north-north-east across the river. Richmond Park is about 1½ miles (2½ km.) to the south-east. General views of the Observatory building and the exposure lawn are to be found in the 1928 volume. The photographs were taken in 1925, but the only changes (before the end of 1929) which need be noted are the substitution of other experimental screens for the small marine screens which were being tested in 1925, and the removal in 1929 of the hedge near the North-wall screen. For the early history of the Observatory reference may be made to papers by S. P. Rigaud (The Observatory 1882, p. 279), R. H. Scott (Royal Society's Proceedings, Vol. 39 (1885), pp. 37–86), C. Chree (The Record of the Royal Society, 1897), and R. S. Whipple (Proceedings of the Optical Convention, 1926).

METEOROLOGY.

The elements dealt with in the following tables are: atmospheric pressure, temperature, humidity, rainfall, sunshine, solar radiation, wind speed and direction, earth temperature, minimum temperature on the grass, level of underground water; there is also a diary of cloud and weather.

For brief descriptions of most of the instruments from which values of the above elements have been obtained and of the methods of tabulating the records, reference should be made to the General Introduction. The following notes supplement, where necessary, the information contained therein.

Notes on Instruments.

Pressure.—The barograph* is mounted in the basement of the Observatory, where the diurnal variation of temperature is very small. The normal position of the instrument has been in the north room occupied by the magnetographs. When the magnetographs were removed and the preparations for the installation of the seismographs were commenced, the barograph was placed in the photographic dark-room (June 16th, 1925). The instrument remained in that position until May 21st, 1928, when it was restored to its original site and electric lighting installed. The barograph magnifies barometric changes in the ratio 1·553 : 1, i.e., the change of ordinate equivalent to a change of 1 mm. in the height of the barometer is 1·553 mm. "Residual corrections," obtained from the control observations taken daily with the Newman barometer at 9h, 15h and 21h, are applied to the hourly measurements. The same correction is applied to all the readings on the same photographic sheet, i.e., generally for forty-eight hours. The individual entries published for the hours of the control observations may differ by ·3 mb. from those observations. The Newman barometer is compared from time to time with the two large mercury barometers, which were set up in 1855 and 1860 respectively and are still recognised as standards. A zero correction is based on these comparisons. The correction + 0·2 mb. (+ ·006 mercury inch) which has been applied for many years, remained in use. Comparisons are made on the assumption that the value of the acceleration due to gravity is $g=981{\cdot}199$ cm./sec^2. This is the value given by pendulum observations.† The departure from the value given for the latitude by Helmert's formula is insignificant. On occasions when a loss of trace occurred, the missing hourly values were derived from the Dines Float Barograph.* There were 53 hours in the year for which this was necessary.

Temperature and Humidity.—The thermograph is mounted in the West Room on the first floor of the Observatory, the thermometer bulbs being exposed in the screen attached to the north wall of the building. This screen has single louvres and the bottom is open. There is an additional flat louvred screen which shields the main screen from direct sunshine when the sun is in the West and not too low. The height of the bottom of the bulbs of the recording thermometers above the bottom of the sides of the screen containing them is 30 cm. in summer, 33 cm. in winter. The height of the bulbs above the top of the artificial mound on which the Observatory stands is approximately 3 metres; the height above the lawn where the rain-gauge is situated is approximately 5 metres. The scale values of the photographic records are not identical for the dry- and wet-bulb curves. For the dry-bulb, tube No. 4 II was in use and the scale value was 1 mm.=0·3336a; for the wet-bulb, the old Falmouth wet-bulb tube (no number) was in use and the scale value was 1 mm. = 0·290a.

The control thermometers, which were graduated and mounted by Messrs. Negretti & Zambra in 1915, had been made and filled many years before and were therefore well seasoned. The National Physical Laboratory certificates dated 1916 give corrections to the nearest 0·05° C., the largest being 0·10°. The thermometers are tested each January in ice. According to tests made in January, 1929, there was no indication of any change of zero. The water for the wet-bulb thermometers used to be supplied from a small open tank inside the screen and it was customary to fill the tank to overflowing several times each day. In November, 1925, a tank was fitted oustide the screen. A tube leads from this tank to two cups from which

* For descriptions of this instrument see *Observatories' Year Book*, 1923, p. 94, and *R. Met. Soc. Q. J.*, 1929, Vol. 55 (229), p. 37.

† A comparison between the values of "g" at Cambridge and Kew Observatory was made during the year 1925 by Sir G. Lenox Conyngham with the assistance of Mr. G. Manley. A similar comparison between Potsdam and Cambridge was made by Prof. Meinesz earlier in the year. These observations are in accord with those made at Kew and Potsdam by Putnam in 1900, from which the value stated above was derived. The value for Potsdam, $g=981{\cdot}274$, based on the observations of Kühnen and Furtwängler, is adopted as the standard of reference.

wicks are taken to the wet-bulbs. A further improvement was made in July, 1926, when a large inverted bottle was set up over the tank. Water flowing from this bottle keeps the level constant in the tank and the cups. The height of the apparatus is adjusted so that water drips slowly from the wet-bulbs. A bottleful of water lasts at least a week. It is found that the bottle survives severe frost.

Control eye-readings of the standard thermometers are taken daily at 9h, 15h and 21h. Residual corrections obtained from the control observations are applied to the hourly measurements of the curves. The same correction is applied to all the readings on the same photographic sheet, i.e., generally for forty-eight hours. The individual entries published for the hours of the control observations may differ by 0·3a from these observations. The larger departures refer to occasions when temperature is oscillating or changing rapidly.

In cases of loss of the dry-bulb record owing to the failure of the electric light or any other cause the readings of a thermograph in a second North-wall screen are adopted. There were 71 hours in the year for which this was necessary.

When the wet-bulb trace is missing or defective, the missing values are derived from the dry-bulb trace and the records of a hair hygrograph. The same procedure is always adopted when the wet-bulb reading is below 273a. 978 hours had thus to be dealt with during the year. Humidity was determined from the dry- and wet-bulb readings by the procedure described in the General Introduction to this Volume.*

It may be noted that during 1929, as in previous years, the temperatures published for Kew Observatory in the Daily Weather Report and elsewhere also refer to the North-wall screen. For the daily and weekly reports the readings of maximum and minimum thermometers exposed in that screen are utilised.

Rainfall.—As from January, 1921, the standard raingauge for the Observatory has been an 8-inch gauge with the deep "Snowdon" funnel. The site is level and protected from wind, principally by hedges about 1½m. high and distant 11 metres to East and 17 metres to West. The readings of this standard gauge are at 7h and 18h. The hourly readings of the Beckley gauge are adjusted to give totals in agreement with the standard gauge.

Sunshine.—The sunshine recorder is mounted on the south parapet of the roof. The same frame has been in use since 1880 and it is believed that the ball has not been changed. The ball is now somewhat yellow. The exposure is satisfactory. The greatest elevations of the sky line in the azimuths in which the sun can rise and set are 1° and 3° respectively.

Solar Radiation.—Observations are made with an Ångström pyrheliometer, which measures the intensity of the direct radiation received from the sun by a surface which is normal to the sun's rays. The observations are made within half an hour of noon on all days except Sundays, provided that the sun is visible and not too much obscured by cloud, fog or thick haze. The conditions of the intervening atmosphere are indicated in Tables 498–509 in the column "sky." The amount of radiation is given in milliwatts per square centimetre in the column headed "total." For conversion to the unit more ordinarily employed abroad, the following relation may be used, 1mw. per sq. cm. = 0·01435 gramme-calorie per sq. cm. per minute. The vertical component, i.e., the direct radiation received per square centimetre of a horizontal surface, is also given.

* Prior to 1926 the tables, based on Glaisher's factors, published in *The Computers' Handbook*, were used.

The Ångström instruments in use are by Rose, Stockholm. No. 24 was in use throughout the year. The ammeter is No. 68956, which was certified at the National Physical Laboratory in 1919.* The readings are evaluated according to Ånström's original instructions.† To bring the readings into accordance with the scale adopted by the Smithsonian Institution, a correction of + 3·5 per cent. would be required.‡

Wind Speed and Direction.—To the end of 1925 the record of wind velocity was based on the readings from the Robinson-Beckley cup-anemograph.‡‡ From the beginning of 1926, readings of the Dines tube-anemograph have been used for all the wind data. The vane of the Dines instrument is at the same level as the cups of the other anemograph, 20 metres above the lawn. There are trees in the neighbourhood reaching greater heights. Those along the river to the west of the Observatory and about 280 metres away average 25 metres. The head of the present Dines instrument, set up at the beginning of the year 1923, is of the Mark II pattern. In the vertical tube there are 80 holes in 4 rows of 20. The diameter of each hole is 3 mm. The connecting tubes, 17 metres long, have the internal diameter 12 mm.

Wind direction is given by a twin-lever recorder attached to the vane of the Dines instrument. In accordance with an old convention, wind direction is not printed when the speed of the wind averages less than 1·6 metres per second, though the present vane is sensitive to lighter currents.

Earth Temperature.—The two thermometers in use were at 30 cm. and 122 cm. The ground in which the tubes for the thermometers are sunk is under grass. The soil is gravel. The site is well exposed. There are, however, three fruit trees about 9 metres to the east and 6 metres high. The bulb of the lower thermometer is 430 cm. above sea level.

Minimum Temperature on the Grass.—The grass minimum thermometer is set at 18h and read at 7h on the succeeding day, the reading being assigned to the day of reading.§ The thermometer is placed with the bulb about 25 mm. above the turf. The exposure is good, there being no obstruction within 76° from the zenith. The thermometer in use throughout the year was M.O. 23006. This thermometer has a spherical bulb, diameter 17 mm.

* In view of the discovery by Marten (*Preuss. Met. Inst. Ann. Rep.*, 1928, p. 64) that errors are likely to be caused by temperature changes produced in a microammeter when sunshine falls on it, it may be noted that the instrument used at Kew is always in shadow.

† Report of the International Meteorological Committee, St. Petersburgh, 1899, p. 57.

‡ R. E. Watson. *Geophysical Memoir*, No. 21, 1923.

‡‡ The cup-anemograph which had been in action since 1869 was dismantled on October 21st, 1929, and a Dines P. T. anemograph of the latest type installed.

§ The hour of the readings to be published in the Year Book was changed from 9h to 7h as from January 1st, 1924.

Notes on Meteorological Tables.

The year was remarkable for the cold winter and for the prolonged droughts. January and February were the coldest experienced since 1895, ice floes appearing on the Thames for the first time since that year.

The lowest temperature was 262·2a (12·6° F) on February 15th. There were 7 "ice days" i.e., days with maximum temperature in the screen below 273a.

The first nine months of the year were remarkable for their dryness, the total rainfall for these months being 184 mm. below normal. March and September were almost without rain.* The heavy rains of November and December, however, with an excess of 122 mm. brought the annual total up to within 10 per cent. of normal.

Sunshine was considerably above normal, the excess amounting to 232 hours.

Diurnal Variation of Pressure and Temperature.—Harmonic Analysis. In accordance with the precedent of the last six years, the first four harmonic components have been computed for each month. The results are tabulated in Tables A and B.

The inequality is supposed to be given by the expression.

$$c_1 \sin (15\ t^\circ + \alpha_1) + c_2 \sin (30\ t^\circ + \alpha_2) + \ldots\ldots$$

t being the time in hours since midnight. The angles α are the phases of the several sine-waves at midnight. The curves are tabulated according to Greenwich mean time but the phases in Table A have been reduced to local mean time. The difference in Longitude between Kew and Greenwich being only 19′ the correction is hardly appreciable in the figures, which are rounded to the nearest degree.

*See "Notes on Rainfall" table No. 485.

Summer	4·052	225	·153	40	·320	30	·103	39

NOTE.—*Winter* comprises the four months, January, February, November, December, *Equinox* the months March, April, September, October, and *Summer* May to August.

Level of Underground Water.—In Table 526 there is given for each day the mean height above sea level of the surface of the underground water. The level actually measured is the surface of water in a pipe which passes through the floor of the basement into the ground. The water level depends mainly on the state of the river Thames. The Observatory is close to Richmond lock, which is half-tidal, and the underground water is in summer a little below the level of low water above the lock (220 cm. above M.S.L). The effects of the spring and neap tides are conspicuous in the fluctuations of level in summer.

Cloud Amount.—The mean cloud amounts for the six hours of observations are given month by month in the diary of cloud and weather. The following means are derived from these data :—

Mean Amount of Cloud from Six Observation Hours.

Month	Jan.	Feb.	Mar.	Apl.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year
Cloud ..	7·9	7·1	4·4	6·8	5·4	6·3	5·5	6·5	4·1	6·4	6·8	6·1	6·1

Mean Amount of Cloud for the Year at the Six Observation Hours.

Hour ..	7h	9h	13h	15h	18h	21h
Cloud ..	6·6	6·6	6·4	6·5	5·5	5·1

Visibility.—The objects used for the classification of visibility are enumerated below. The Observatory is on very low ground. The view is bounded on the south-east by Richmond Hill and on the west by the trees near the river. For object H a church tower seen through trees and with high ground behind it has to be used. There is no conspicuous object at the appropriate distance to serve as I, and interpolation is necessary. The object J is in London and is therefore more affected by atmospheric pollution than the other objects.

ATMOSPHERIC ELECTRICITY.

The systematic observations in atmospheric electricity are devoted to potential gradient, air-earth current and ionization. In the case of potential gradient there is continuous autographic registration ; the other elements are observed each afternoon when conditions are favourable.

Potential Gradient.—The Kelvin water-dropper electrograph has been housed since 1915 in a low building known as the Clinical House. The pipe carrying the jet projects through a hole in a window and is adjusted so that the point where the jet breaks into spray is 1·50 m.* from the window and 1·73 m. above the pool into which the water falls.† The electrogram is a record of the difference of potential between the ground and the point where the jet breaks. The aim is, however, to obtain the potential gradient in the open. For this purpose observations are made at a site in the Observatory garden. The apparatus for these " absolute " observations consists essentially of a long insulated rod carrying at the end a lighted fuse, which is connected to an electrostatic voltmeter. Readings are taken with the fuse at one metre and at two metres above the ground, the grass on which is kept short. The observations are taken about noon on all convenient dry days. From the observations the ratio of the potential gradient in the garden to the potential recorded by the electrograph is computed. Such a ratio is given for each month in Table 541.

The water dropper was out of action, owing to frost, from February 11th to March 3rd. For this period of inaction, however, the values of potential gradient are derived from a subsidiary electrograph consisting of a radio-active collector attached to a Dolezalek quadrant electrometer which was run in the old Magnetic Hut.

During the year‡ two electrostatic voltmeters, No. 1684 and No. 1685, were used for the absolute observations. The voltmeters and also the electrograph are calibrated at frequent intervals by means of a Cambridge and Paul potentiometer, a high tension dry battery being used as a source of potential difference.

The data appearing in Table 540 include the electrical character figure assigned to each day from the consideration of the electrograms. Of the character figures, 0 denotes the absence of negative potential, 1 implies the existence of negative potential at one or more times during the day but with a total duration of less than 3 hours, while 2 implies the existence of negative potential with a total duration of 3 hours or more. As a negative potential gradient hardly ever occurs except when rain is in the neighbourhood, character 0 occurs on dry days and character 2 on days with continuous rainfall.

---

* This measurement was made in July, 1926. It is believed that there has been no appreciable change since 1915.

† This height is regulated and has been kept the same.

‡ As from January 1st, 1923, the electrostatic voltmeters took the place of the Kelvin portable electrometer, No. 81, previously used for this purpose.

The present criteria for character figures were adopted as from the beginning of 1914. Correcting for missing days, the average frequency of character figures 0, 1, and 2 during the years 1914–1927 inclusive were 185 : 140 : 40. The corresponding figures for 1929 are 211 : 119 : 35. In accordance with a resolution of the International Union for Geodesy and Geophysics (Section for Terrestrial Magnetism and Atmospheric Electricity : Prague Meeting 1927) tabulations of the duration of negative potential gradient are included in the present issue of the Year Book. The total duration of negative gradient is given for each day for which the electrographic record is satisfactory.

Table 541 gives daily data derived from measurements of the electrograms. They represent means for 60-minute intervals centred at the exact hours 3h, 9h, 15h, and 21h G.M.T. On occasions when the trace was defective, either through failure of insulation or some other cause, values of potential gradient have been omitted. On some occasions the curve, though existent, is so oscillatory that no satisfactory estimate is possible of the mean value of the ordinate. Such occasions are indicated by the letter *z*. If there is no doubt as to the sign of the hourly mean value, though a numerical measure is unobtainable, the sign is indicated by a + or a − attached to the *z*. The symbol $z \pm$ indicates that there were oscillations on both sides of the zero line, and that the sign of the mean value was uncertain.

The extreme hourly mean values in Table 541 are 1215 v/m at 9h. on March 5th and — 680 v/m at 15h. on November 16th. The former value is representative of foggy conditions ; on this particular occasion the fog developed in the early morning after a fine evening. The potential gradient started rising gradually at 5h., reached a maximum at 9h. and then fell gradually until 13h. The fog cleared at 10h. 30m. The extreme negative potential of November 16th was associated with continuous rain and occasional sleet. The potential was persistently negative from 10h. to 19h.

Of the two sets of mean monthly values at 3h, 9h, 15h and 21h given in Table 541 at the foot of each month's data, the first set (*a*) represents the arithmetic means of all the positive potentials in the column, the second set (*b*) represents the algebraic mean derived from all days on which all four hours were represented. The last line gives the mean value for each month as derived from the (*a*) and the (*b*) values respectively.

For reasons explained in the 1922 Year Book, it is believed that the values (*a*) may be expected to give approximately the true monthly mean from all days when negative potentials are excluded, while the values (*b*) may be expected to give approximately the true monthly mean when negative potentials are included. But a reservation is necessary in both cases, for the highly oscillatory occasions such as are met with during thunderstorms have been omitted, and this omission may have a sensible effect.

If the monthly means in Tables 541 and 542 be compared, it will be found that the quiet day mean is in excess of the means (*a*) and (*b*) in ten months out of the twelve. In four months, January, May, November, and December, the excess of the quiet day mean over the mean (*a*) is notable. For the year as a whole, allowing equal weight to the twelve months, the quiet day mean, the mean (*a*) and the mean (*b*) are respectively 338 v/m, 321 v/m and 307 v/m. The corresponding values for 1928 were 298 v/m, 301 v/m and 282 v/m.

As to comparison with earlier years it is to be noted that the present method of making the "absolute" observations was initiated at the beginning of 1910. Since then there has been no considerable change in the exposure at the control station.* The annual mean potential gradient for selected quiet days is available from that date onwards.†

1910	310 v/m	1917	354 v/m	1924	329 v/m
11	301 v/m	18	346 v/m	25	326 v/m
12	300 v/m	19	331 v/m	26	279 v/m
13	335 v/m	20	315 v/m	27	315 v/m
14	345 v/m	21	281 v/m	28	298 v/m
15	354 v/m	22	318 v/m	29	338 v/m
16	367 v/m	23	318 v/m		

The average for the 20 years is 323 volts per metre.

The mean for 1926 is a minimum. Along with the low value for 1921 it was probably to be attributed in part to the exceptional atmospheric conditions prevailing during the coal strikes of those years. Apart from these abnormalities a smooth change of potential gradient is to be noticed. In fact, the figures have been quoted‡ by Dr. Bauer as evidence for a connection between atmospheric electricity and solar activity.

The diurnal inequalities and the mean monthly and annual values in Table 542 are based on the curves of quiet days selected from those entirely free from negative potential. Other objects aimed at in the selection of the days are freedom from large irregular movements, absence of indications of inferior insulation in the electrograph, and the avoidance, so far as possible, of large non-cyclic changes. The quiet days numbered 10 in each month; but to complete that number in December it was necessary to include one 24-hour period which did not commence at midnight, while for six days in February the data were obtained from the subsidiary electrograph.

Except in these cases the non-cyclic change is given explicitly in Table 542, so that anyone who may desire to reproduce the figures as they were before the non-cyclic correction was applied can easily do so.

All the inequalities show a well marked double oscillation with minima in the early morning and early afternoon, maxima in the late morning as well as in the evening. The diurnal inequality for the whole year shows the higher maximum at 9h, the lower minimum at 4h. This is not the case in every year. The hours of the extremes and the range of the inequality is given for each year from 1910 in the following list.

Year.	Max. hr.	Min. hr.	Range v/m	Year.	Max. hr.	Min. hr.	Range v/m	Year.	Max. hr.	Min. hr.	Range v/m
1910	20	4	138	1917	20	4	154	1924	20	4	133
1911	9	4	154	1918	20	2	139	1925	19	3	129
1912	9	4	149	1919	8	4	124	1926	20	4	118
1913	19	3, 4	160	1920	9	3	122	1927	19	3	129
1914	20	3	169	1921	20	3, 4	132	1928	9	3	124
1915	19	5	173	1922	20	4	144	1929	9	4	137
1916	20	4	151	1923	9	4	160				

It will be seen that the range has been considerably lower in most recent years than it was in the years 1911 to 1917.

† Estimates for the years 1898–1909 are given by Chree, *Phil. Trans.* A (1915) p. 141. The change of site of the electrograph in 1915 is discussed in *Hourly Values*, 1916.

‡ Washington, Carnegie Institution. Researches of the Dept. of Terr. Mag., Vol. V. (1926) pp. 361–384.

If the inequalities for the year and the seasons are compared with the corresponding inequalities for atmospheric pollution given in Table 544, the remarkably close similarity in the hours of occurrence of the principal maxima and minima noted in previous years is not borne out. There is, however, the same marked double oscillation throughout the day in both elements, a principal maximum or minimum of one falling at the same time as the secondary maximum or minimum of the other.

Conductivity and Air-earth Current.—To determine the current flowing from air to earth, the conductivity of the atmosphere at one metre above the ground is measured by means of the Wilson universal electrometer.* For calculating the conductivity at 15h. four observations, each giving the leakage from a charged plate in 5 minutes, are averaged. The product of the conductivity so determined and the potential gradient at 15h (as given in Table 541) is taken as the measure of the air-earth current. The conductivity is not observed during rain nor when the potential gradient is negative. Data are available for about one-third of the days of the year 1929.

In Table 539 we have ventured to use λ_+ as the symbol for the Wilsonian conductivity, so implying that the conductivity measured is that due to positive ions. This interpretation of the observations is not accepted by all physicists.

The conditions under which the air-earth current is measured are maintained as uniform as possible, but they differ from the conditions under which the vertical current passes from the air to the earth in the absence of the apparatus. The presumption is that the results obtained would require to be multiplied by a factor to represent the true air-earth current.† The monthly mean of the observed values of the current varied from 47 in January to 109 in September in terms of the unit 1×10^{-18} ampere per square centimetre. Allowing equal weight to each month we find that the mean for the year in terms of the above unit is 82. The mean derived directly from the 140 observations is 84. There is very little difference from the corresponding values for other years.

There is some doubt as to the comparability of observations made with the Wilson apparatus and other estimates of the air-earth current. Determinations based on separate measurements of the conductivity for positive and negative electricity have yielded on the continent averages of about 2×10^{-16} amperes per square centimetre. On the hypothesis that it is only λ_+ that governs the transport of electricity from air to ground this estimate must be reduced to 1×10^{-16} amperes per square centimetre.

Ionic Charges.—Table 539 also gives the volume-charges carried by such positive and negative ions (including all of the more mobile type) as are caught by the Ebert apparatus.‡ The instruments are exposed in the open on a stone pedestal 1 metre high, and the observations extend over some 20 minutes near 15h, being simultaneous with the experiments with the Wilson electrometer.

Normally, two Ebert instruments are in use, one charged positively, the other negatively, the signs alternating from day to day. The initial voltage is about 180.

---

* *Proceedings of the Cambridge Philosophical Society*, Vol. 13, p. 184 (1906).

† When the current passing into a metal plate at ground level is taken as the standard the factor is found to be about 1·2. A discussion of this question has been published in a memoir by Dr. R. E. Watson. —*Geophysical Memoirs, No.* 45. 1928.

‡ *Physikalische Zeitschrift*, Vol. 8, No. 8, p. 246 (1907).

In interpreting the observations it is to be borne in mind that even in pure mountain air the greater part of the electric charge is carried by the sluggish "Langevin" ions. In less pure air a still higher proportion of the ions is immobilised and there is a decrease in the number of the small ions, i.e., of ions such as are most effective in producing the conductivity of the atmosphere.

As is usual at Kew the highest values of the measured ionization occurred during the summer half of the year. The averages for the year were + 65 and − 48 × 10^{-18} coulomb per c.c. According to Millikan's experiments* the ionic charge is 15·9 × 10^{-20} coulomb, so that these averages correspond respectively with 400 positive and 300 negative ions per c.c. These averages are much lower than those obtained in clean country air. According to Bauer and Swann† the means for the principal observations reported at land stations before 1917 were 737 positive and 668 negative ions per c.c.

ATMOSPHERIC POLLUTION.

The Owens atmospheric pollution recorder or air filter No. 1‡ is situated in the Clinical House, and the level of the intake is about 1½m. above that of the adjacent ground. The weight of the pollution is not obtained directly but is deduced from shade numbers 0, 1, 2, etc., assigned to the deposit left on the filter paper through which the air is drawn. The equivalents of the shade numbers are allotted in accordance with the results of an investigation carried out for the Atmospheric Pollution Committee by Mr. J. G. Clark.§ When the normal volume of air, 2 litres, is aspirated (it is drawn through a hole 3·2 mm. in diameter) shade number 1 answers to 0·32 milligrams per cubic metre. The Owens apparatus was designed in the first place for dealing with the air of cities and the amount of pollution at the Observatory is usually so small that the shade recorded when the 2 litres are aspirated is either 0 or 1.

Preliminary experiments with a spare recorder having justified the assumption that increasing the volume of air would increase the shade number in proportion an auxiliary tank was brought into use at the beginning of July, 1928. With this tank in operation each spot on the filter paper corresponds with 6·4 litres of air. The unit shade is therefore equivalent to 0·1 mg./m³. When fog prevails the auxiliary tank is put out of action and the unit shade reverts to the value 0·32 mg./m³.

This improvement in the recording system must of itself introduce a discontinuity in the published data. It is anticipated however that the results will be much more reliable.

In this connection it is to be noted that new scales of shades were taken into use on the following dates :—

June 7, 1925 ; July 1, 1926 ; and (retrospectively) January 1, 1928.

The highest estimate of pollution was 4·8 mg./m³ on November 15th at 17h. There were 43 days on which the pollution reached 1·0 mg./m³ ; the number of hours credited with 1·0 mg./m³ or more being 312. The months in which these days and hours occurred are given in the table in the margin.

	days	hours
Jan.	6	49
Feb.	14	100
Mar.	14	112
Nov.	6	43
Dec.	3	8
	43	312

Table 543 gives mean hourly values derived from all the days of the month for which complete records were obtained. There were 353 such days in the year. The highest and lowest of these hourly values are in heavy type.

* Phil. Mag. (6) 34 (1917) 3.

† Washington, Carnegie Institution. *Researches Dept. of Terr. Mag.*, Vol. III (1917) p 411.

‡ A description of the instrument is given in the *Report of the Advisory Committee for Atmospheric Pollution*. 4th Report, 1917–1918 (p. 20).

§ London, M.O. *Report of the Advisory Committee for Atmospheric Pollution*. 3rd Report, 1916–1917, (p. 20).

Table 544 gives diurnal inequalities derived from the data in Table 543 after the application of non-cyclic corrections. The principal reason for computing the diurnal inequalities was to facilitate comparison with the corresponding diurnal variations in barometric pressure and the potential gradient of atmospheric electricity.

The mean values computed for the several years since the recorder has been in operation are given in the following table, together with the means for the summer months (May to August) for the equinoctial months (March, April, September, October) and for the winter months. The unit is 1 mg/m³.

	1921	1922	1923	1924	1925	1926	1927	1928	1929
Summer	·13	·27	·27	·25	·15	·08	·06	·07	·06
Equinox	·27	·45	·30	·50	·24	·25	·13	·15	·18
Winter	·53	·46	·35	·39	·39	·27	·24	·23	·30
Year	·31	·39	·31	·32	·26	·20	·14	·15	·18

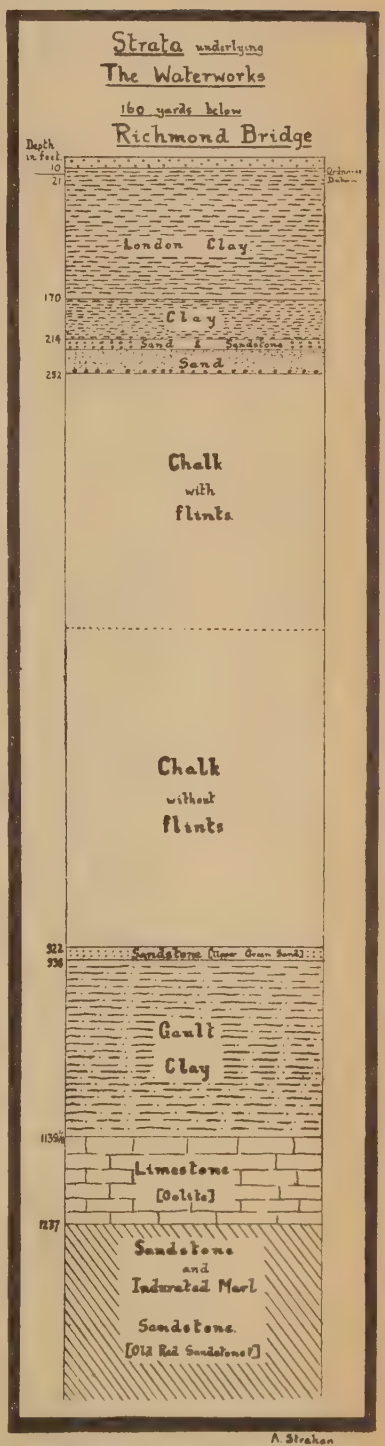
In any discussion of these mean values it should be borne in mind that before the introduction of the auxiliary tank the great majority of estimates were shade 0 or shade 1. To discriminate between these two shades is difficult, and the decision depends on the " personal equation " of the observer as well as on the colour of the scale of shades. Some change in standard from year to year has been inevitable.

The nature of the diurnal variation is most easily recognised in Table 544. There is always a well defined minimum during the night and another in the early afternoon. The first maximum of the day usually occurs about 9h and the second one follows about 12 hours later. This double oscillation is apparently due to two causes, the variation in human activity in producing pollution and the variation in the wind which disperses it. In 1929 the principal maximum was in the afternoon in April and from October to December; in the forenoon in the remaining months. The principal minimum occurred in the afternoon from March to September; in the early morning in the remaining months. Curves illustrating the diurnal variation of atmospheric pollution will be found in the Annual Reports of the Advisory Committee on Atmospheric Pollution and in a paper by Dr. F. J. W. Whipple in the Quarterly Journal of the Royal Meteorological Society, Volume 55 (1929), No. 231.

SEISMOLOGY.

Notes on Instruments.—The seismographs, three Galitzin pendulums with galvanometric registration, were transferred from Eskadelmuir Observatory during the latter part of 1925 and have been in regular operation since the beginning of 1926. Earth movements in the north, east and vertical directions are recorded. The pendulums, which are in the old magnetograph room, are mounted on a massive concrete pillar, separated from the floor. The galvanometers and recording apparatus are accommodated on slate slabs in the old seismograph room, which housed the Milne instrument until it was put out of action on June 17th, 1925. To eliminate temperature variation as far as possible, the windows of the pendulum room are provided with triple glass and also shielded by louvred screens from direct sunshine which might fall on them morning and evening. The annual range of temperature variation is about 10° C. and the mean daily range about 0·2° C.

The concrete pillar rests on gravel. The underlying geological strata are shown in the diagram on this page. The diagram is based on the results obtained * in sinking a well near Richmond Bridge. The Richmond boring terminated at a depth of 440 metres in Old Red Sandstone. At Stonebridge Park, 8 km. to the north, a boring was carried down † to a depth of 600 metres, the last 280 metres being in Old Red Sandstone. There is no information as to deeper strata near Richmond. It may be noted, however, that the sandstone beds dip at about 30° and that a boring at Little Missenden, Bucks, entered Silurian rocks at a depth of 370 metres with no evidence of the presence of Old Red Sandstone.



For detailed description of the Galitzin seismograph and for particulars of interpretation of the records, reference may be made to Fürst B. Galitzin's "Vorlesungen über Seismometrie" (Leipzig, 1914), or to G. W. Walker's "Modern Seismology" (London, 1913).††

Timing is controlled be a half-seconds clock (Morrison 8587) which is rated daily by comparison with the Greenwich wireless time-signal relayed from Daventry. Time breaks are made electro-magnetically every minute and seismometric readings can be determined to the nearest second.

The free periods of the galvanometers (T_1), were determined in November, 1925, and were found to have suffered very little change since the original determinations at Eskdalemuir were made. The lengths of the simple equivalent pendulums (l), are assumed to have remained unaltered. These constants are as follows :—

	N	E	Z
T_1	24·68 sec.	24·80 sec.	13·04 sec.
l	118 mm.	118 mm.	360 mm.

N, E, and Z indicate the north, east and vertical components respectively.

The values of the other constants which are used for deriving the scale values were determined in March and September for the vertical pendulum, and in September for the horizontal instruments. In the case of the horizontal instruments it was found that the magnifications agreed closely with those obtained from the previous tests in June, 1928. In order to diminish the sensitivity of the vertical pendulum to temperature changes the steel controlling spring was replaced in May, 1928, by one made of elinvar, an alloy which has a temperature coefficient of elasticity about one tenth that of steel.‡ A detailed report on the behaviour of the spring has been published in a paper § by F. J. Scrase. The difficulties usually associated with the operation of the vertical pendulum have been greatly diminished. Some adjustments to the vertical pendulum were carried out on September 10th.

The table given below summarises the values of the constants obtained from the standardisation tests. T is the free period of the pendulum, μ is a damping co-efficient which vanishes when the free movement of the pendulum is just aperiodic, A is the length of the beam of light from the galvanometer mirror to the recording drum (usually about 1100 mm), and k is the "transmission" factor. The quantity $\frac{kA}{\pi l}$ may be regarded as a relative measure of the nominal magnification. $\frac{kAT}{4\pi l}$ is the magnification factor for regular earth movements with a period equal to that of the pendulum.

In windy weather the seismographs, especially the horizontal components, are affected by slow oscillations, which are attributed to the tilting of the ground, the movement being conveyed through the foundations of the Observatory. On occasions the reading of an earthquake record is rendered very difficult, if not impossible, by these irregular disturbances.

Notes on Tables.—The *Seismological Diary*, Table 545, contains the particulars of the earthquakes recorded at the Observatory. The notation employed is as follows :—

P is the normal first phase (longitudinal waves). Special cases of P occur when the waves are reflected from (PcP) or penetrate (P′) the earth's central core.

PR_1, PR_2 . . . are longitudinal waves reflected once, twice . . . near the earth's surface.

S is the normal second phase (transverse waves). ScPcS is a special case of S in which the wave penetrate the central core and pass through it as longitudinal vibrations.

PS and PPS are waves which suffer a change or changes from longitudinal to transverse oscillation or vice versâ, on reflection near the surface.

SR_1, SR_2 . . . are transverse waves reflected once, twice . . . near the surface.

L indicates long waves (surface waves).

i is the sudden commencement of a phase. *e* means a gradual or indistinct commencement. These letters are used as prefixes to the phase symbols, but where the character of the phase is not assignable the letters are used as independent symbols. When the commencement of a phase is moderately clear the prefixes are not used.

The suffixes N, E, Z indicate that the estimates refer to the records from the north-south, east-west and vertical seismographs respectively. The absence of all these suffixes indicates that the estimates refer to all three records.

All times entered against the above phases are the times of arrival of the phases at the station.

m_1, m_2 . . . are successive prominent maxima of sinusoidal waves occurring in the preliminary phases. M_1, M_2 . . . are successive prominent maxima occurring during the principal or surface phase.

The period is the duration of a double oscillation (to and fro movement).

A_N, A_E, A_Z are the amplitudes, in microns (μ=0·001 mm.), of the components of the true displacement of the ground from the position of rest. Displacements to the north, east and upwards are regarded as being positive. When successive positive and negative displacements have the same magnitude the time of occurrence is given for the positive one. When no sign is given the measurement refers to a long group of waves the amplitudes of which are the same.

The following formulæ due to Galitzin are employed for computing the times of the maxima and the amplitudes of sinusoidal waves :—

(1) Lag of the displacement shown by the galvanometer after the maximum displacement of the ground

$$\tau+\tau_1=\frac{T_p}{2\pi}\left[\tan^{-1}\frac{2u\,(1-\mu^2)^{\frac{1}{2}}}{u^2-1}+\tan^{-1}\frac{2u_1}{u_1^2-1}+\frac{\pi}{2}\right]$$

each inverse tangent being taken as between 0 and π.

(2) Magnification of record =

$$\frac{k\,A\,T_p}{\pi l}\cdot\frac{1}{(1+u^2)(1+u_1^2)\{1-\mu^2 f(u)\}^{\frac{1}{2}}}$$

where T_p is the period of the earth wave considered,

$$u=\frac{T_p}{T},\quad u_1=\frac{T_p}{T_1},\quad \text{and } f(u)=\left[\frac{2u}{1+u^2}\right].$$

Δ is the distance in kilometres of the epicentre measured along the arc of the great circle passing through the station. This distance is derived from the interval between P and S, by the tables, due to Zeissig, given in Klotz's "Seismological Tables" (Publication of the Dominion Observatory, Ottawa, Vol. III, No. 2). The azimuth of the epicentre (0° to 360°) is measured from north through east. When an estimation of the azimuth is possible, it is used, together with Δ, for provisional determination of the co-ordinates of the epicentre. In other cases where co-ordinates are given, the information has been obtained from other sources ; the origin of the determination is inserted in brackets.

Brackets enclosing figures or phase symbols indicate that the information is uncertain.

The Diary contains some amendments to the information which has already been issued in the Observatory Seismological Bulletin. Attention is drawn to revised readings for the disturbance on June 3rd, in which case misinterpretation of the phases led to an estimate of the epicentral distance which was quite incompatible with information received subsequently.

The total number of shocks recorded during the year was 320. The phases being sufficiently well defined, estimates of the epicentral distances were obtained for 74 shocks, whilst in 6 cases the records of the initial impulses were sufficiently sharp to allow of computations of azimuth and so of estimates of the co-ordinates of the epicentres. There were 12 earthquakes which produced a disturbance at the observatory with an amplitude exceeding 0·1 mm. in a horizontal component. These earthquakes originated in the Sea of Okhotsk (January 13th), in the Atlantic Ocean (February 22nd, June 27th, November 18th), near the Aleutian Islands (March 7th, July 7th—8th, December 17th), in Persian Turkestan (May 1st), in Asia Minor (May 18th), in the Pacific Ocean near Alaska (May 26th—27th), in New Zealand (June 16th—17th), and near the Caroline Islands (November 15th).

For comparison the statistics for all the years in which the Galitzin seismographs have been in operation at Kew Observatory are given :—

	Shocks recorded.	Epicentral distances.	Azimuths. estimated	Shocks exceeding 0·1 mm.
1926	306	55	—	10
1927	314	78	6	9
1928	339	97	19	18
1929	320	74	6	12

Microseisms.—In Table 545 are given the amplitude (A) and period (T_p) of the microseisms shown by the north component seismograph on each day at 0h, 6h, 12h, and 18h.* On a few occasions (less than 2 per cent. of the total number) when the north component record was not available measurements of the east component

* For the year under review microseisms were measured at eight hours daily (0h., 3h., 6h.—etc. with a view to investigation of diurnal variation.

record have been included. The group of waves of greatest amplitude occurring in the 30 minutes centering at the hour in question is selected, and the amplitude tabulated is the mean obtained from the three largest complete waves in that group. The period is derived from a measurement made on the same group, but the procedure adopted in 1926 and 1927 was slightly modified from January 1st, 1928, in order to diminish the tendency on the part of the tabulator to give preference to certain periods.* The total time, to the nearest second, for a number of complete consecutive waves is measured, the number of waves being chosen so that the time is between 23 and 30 seconds. The period is then derived from the following division table :—

Number of Waves.	Time interval in seconds.							
	30	29	28	27	26	25	24	23
3	10	9·7	9·3	9·0	8·7	8·3	8·0	7·7

7	4·3	4·1	4·0	3·9				
8	3·7	3·6	3·5					
9	3·3	3·2	3·1					
10	3·0	2·9	2·8					
11	2·7	2·6						
12	2·5							

In computing the mean period occasions of zero amplitude are omitted. The mean values of amplitude and period for each month of 1929 and for the year, together with the corresponding values for 1926, 1927 and 1928 are given below :—

MICROSEISMS—MONTHLY AND ANNUAL MEANS.

	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year
1926.													
Amplitude (μ)	2·3	1·7	1·8	1·1	0·5	0·4	0·5	0·6	0·5	0·8	1·7	1·6	1·1
Period (secs.)	6·3	6·5	6·5	5·6	4·7	4·6	4·6	4·7	5·2	4·9	6·1	6·2	5·5
1927.													
Amplitude (μ)	2·8	1·6	1·7	1·1	0·5	0·6	0·5	0·8	0·9	1·1	1·9	2·5	1·3
Period (secs.)	6·6	6·1	5·8	5·5	4·5	4·6	4·0	4·7	4·8	5·1	6·1	6·3	5·3
1928.													
Amplitude (μ)	2·9	2·6	1·3	1·1	0·4	0·8	0·4	0·7	0·7	1·4	2·1	1·6	1·3
Period (secs.)	7·1	6·7	5·6	5·5	4·6	4·6	4·7	4·3	5·0	5·9	6·0	6·0	5·5
1929.													
Amplitude (μ)	1·5	2·1	1·1	0·8	0·8	0·6	0·4	0·6	0·9	1·4	2·1	3·0	1·3
Period (secs.)	6·3	5·8	6·1	5·0	5·0	4·4	3·9	4·1	5·2	5·1	6·0	6·8	5·3

* F. J. W. Whipple and F. J. Scrase, "On the Frequency of Microseisms of Different Periods at Eskdalemuir and at Kew." Mon. Not. R.A.S., Geophys. Suppl. II. No. 2 (1928).

Readings in millibars at exact hours, Greenwich Mean Time.

440. Richmond (Kew Observatory) : H_b (height of barometer cistern above M.S.L.) = 10·4 metres. **January, 1929.**

Station Level

NOTE.—When pressure exceeds 1000 mb. the leading figure 1 is not printed, *i.e.*, 1005·6 mb. is written 005·6. This rule does not, however, apply to monthly means.

Readings in millibars at exact hours, Greenwich Mean Time.

442. Richmond (Kew Observatory) : H_b (height of barometer cistern above M.S.L.) = 10·4 metres. **March, 1929.**

NOTE.—When pressure exceeds 1000 mb. the leading figure 1 is not printed, *i.e.*, 1005·6 is written 005·6. This rule does not, however, apply to monthly means.

Readings in degrees absolute at exact hours, Greenwich Mean Time.

455. Richmond (Kew Observatory) : North Wall Screen : h_t (height of thermometer bulb above the ground) = 3·0 metres.

January, 1929.

485. Richmond (Kew Observatory). NOTES ON RAINFALL. **1929.**

Absolute Droughts.

The *British Rainfall* definition of an absolute drought is a period of at least 15 consecutive days on none of which the precipitation exceeds 0·1 mm. According to this definition there were two absolute droughts during the year, from February 27th to March 24th and from August 23rd to September 28th.

Dry Periods.

The 25th, with 0·4 mm. was the only day in March on which 0·1 mm. was exceeded. The total for the month, 0·7 mm., is the smallest monthly sum recorded since 1856, when systematic measurements of rainfall commenced at Kew. September, with 4·0 mm., was the driest September on record, precipitation exceeding 1 mm. on only two days.

Wet Periods.

Rain fell on every day from November 22nd to December 15th, thus constituting a "Rain Spell." Rainfall exceeded 1 mm. on every day from November 23rd to December 12th. This constitutes a "Wet Spell."

Rainfall Duration.

There were 45 calendar days on which the duration was registered as 0·1 to 1·0 hour, 30 days with 1·1 to 2·0 hours, 47 days with 2·1 to 6·0 hours, 15 days with 6·1 to 12 hours and 3 days with more than 12 hours.

Continuous Falls.

On November 28th it rained continuously for 12hr. 24m.

Heavy Falls in Short Periods.

The most outstanding fall of the year occurred during a thunderstorm on July 20th, when 36·1 mm. fell in 66 minutes.

The following list includes all dates on which 5 mm. fell within an hour.

	July 20 h m	July 31 h m	Aug. 1 h m	Aug. 16 h m	Oct. 2 h m	Oct. 24 h m	Nov. 10 h m	Nov. 16 h m
5 mm. ...	2	36	10	27	48	22	26	54
10 mm. ...	7	—	—	1 18	—	1 36	—	3 0
25 mm. ...	30	—	—	—	—	—	—	16 12

Amounts, in millimetres, for periods of sixty minutes between the exact hours, Greenwich Mean Time.

486. Richmond (Kew Observatory) : H_r (height of receiving surface above M.S.L.) = H (height of station above M.S.L.) + h_r (height of receiving surface above ground) = 5·5 metres + 0·53 metres. **January, 1929.**

Hour. G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 5 metres + 20 metres.

March, 1929.

Hour. G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 5 metres + 20 metres. **May, 1929.**

Hour G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 5 metres + 20 metres.

September, 1929.

13.	14.	15.	16.	17.	18.	19.	20.	21.	22.	23.	24.	Mean	Day

Direction expressed in degrees from North (E=90°, S=180°, W=270°, N=360°). Speed in metres per second.

520. Richmond (Kew Observatory): H_a (height of vane of anemograph above M.S.L.) = Height of ground above

Dines Anemograph from Jan., 1926.

(*a*) Mean from all positive readings.
(*b*) Mean from all complete days, using both positive and negative readings.
NOTE.—The Potential Gradient is reckoned as positive if the potential increases upwards. For indeterminate potential gradient the following notation is used :—$z+$, Indeterminate, positive value ; $z-$, Indeterminate, negative value ; $z\pm$, Indeterminate in magnitude and sign.

POTENTIAL GRADIENT (reduced to level surface): DIURNAL INEQUALITIES (in volts per metre).

The departures from the mean of the day are adjusted for non-cyclic change.

SELECTED QUIET DAYS.

INTRODUCTION.

Notes on the tables of Upper Air Temperatures obtained from soundings with registering balloons at Richmond and Sealand, 1929.

The tables are presented in the same form as those appearing in the Observatories' Year Book for 1928. The Dines pattern meteorograph was employed solely as before. About 37% of the instruments used had been constructed in the Observatory workshop, the rest being purchased from outside contractors.

The method of operation remained the same as in recent years. A full description will be found in "The Dines Balloon Meteorograph and the method of using it."* In the computation of pressure-heights the graphical method was employed, checked as to its main features by an arithmetical process. A value of gravity constant with height was assumed, and equal to 981·2; the effect of humidity on the density of the air was neglected.

A total of 48 soundings were made during the year, 32 from the Aviation Service Station of the Meteorological Office at Sealand Aerodrome and 16 from Kew Observatory. In the cases of 36 of these soundings the instruments were found and returned, the rest being lost. The choice of station from which a sounding was made was generally determined in view of the probable direction and length of the run of the balloon.

The ventilation of the Dines meteorograph is effected solely by the natural draught produced by its vertical velocity. The vertical velocity of the rising balloon was of the order of 220 metres per minute in about 40% of the successful soundings and of the order of 310 metres per minute in the remaining 60%. After the balloon had burst the meteorograph normally fell at the rate of about 700 metres per minute.

As regards temperature, unless stated to the contrary the mean of the records on the ascent and descent was employed entirely in computing the published figures. Except in one or two cases of daylight soundings in which a small vertical velocity of the balloon was employed, and in a limited region near the top of another daylight sounding, the difference between the two records did not in general exceed 4a., with a mean of about half that value. Whenever direct evidence is available it is almost always found that in the troposphere the descending record is the colder of the two. An analysis of a large number of British soundings has led to the conclusion that as far as the troposphere is concerned this effect is mainly due to a temperature lag of the thermograph member, and that the mean of the two records gives in general a close approximation to the true air temperature.† Occasionally in exceptional circumstances it is deemed best to give greater weight to one record than to the other, or to publish the data from one record only. All such occasions are mentioned in the notes, they generally refer either to occasions of strong solar radiation when the less vigorous ventilation of the meteorograph on the ascent makes that record less reliable than that of the descent, or to the lowest layers of the troposphere only.

---

† See also :—Memoirs of the Indian Meteorological Department. Vol. XXIV. Part V. By J. H. Field.

In the case of high soundings made during the day-time a pronounced rise of temperature is sometimes observed over about a kilometre at the extreme top. There is good evidence that this is a fictitious effect due to solar radiation and that the ascent is a great deal more affected by it than the descent. The rise of temperature in such cases is therefore usually ignored, and in addition greater weight is given to the descent than to the ascent in the upper parts of such records as show an unusually large difference between them. All occasions on which such selection has been made are specifically mentioned in the notes. An account of this phenomenon is to be found in " Memoirs of the Royal Meteorological Society," Vol. 2, No. 18. By L. H. G. Dines.

In most cases during 1929 the meteorograph was fitted with a hair hygrograph. Only one record of relative humidity in each case has been published, which unless specifically mentioned to the contrary in the notes is that of the ascent. The record of the descent appears to be the less reliable for two reasons, first that the previous exposure of the hair to extreme cold and dryness makes it more sluggish in response to changes in the relative humidity, second that the higher velocity at which the meteorograph falls increases the lag in its response reckoned in terms of height. The hygrometer readily shows changes in the relative humidity in the lower part of the troposphere, but the absolute value of its readings may be subject to an uncertain error of five or more on the percentage scale. Below a temperature of 250 a. it seems very doubtful if in the ordinary way the record has any meaning, and the figures for the higher parts of the atmosphere have not therefore been published.

In order to ensure as far as possible that the hygrograph works under standard conditions, it is normally exposed to a saturated atmosphere for ten minutes about an hour before the sounding is made.

The method employed in calibrating the hygrograph is as follows :—It is first immersed in either water or a saturated atmosphere for at least ten minutes, and a mark made by the scriber on the record plate which is taken as corresponding with steady saturated conditions. It is then taken out, roughly dried to remove superfluous water, and placed as soon as possible in a testing chamber through which a current of air flows continually. The relative humidity of the air stream is next reduced in two or more stages to a minimum value of about 20%, plenty of time being allowed at each stage for the conditions to become steady. When in each case steady conditions have been attained a mark is made by the scriber. The object of the test is to obtain two marks at relative humidities near 25%, and in such case the total time taken is about 25 to 30 minutes from the instant when the hygrograph is removed from the water in the first place. If the relative humidity is reduced in more than two stages the total time taken is greater, allowing about ten minutes per stage.

When the contraction of the hair corresponding with a relative humidity of 25% has been determined in the manner described, the contraction throughout the scale under the conditions met with in the sounding is assumed to follow an empirical law, which has been determined from the average behaviour of a number of hairs. This law is expressed in the following table, in which the quantity k is defined as the contraction of the hair at 25% from its saturated length expressed as a fraction of the saturated length.

Relative humidity %	25	30	40	50	60	70	80	90	96
Contraction of hair. / Saturated length.	·97k	·88k	·73k	·59k	·45k	·32k	·20k	·08k	·00

The calibration is carried out at temperatures above 288 a. and it is assumed that the thermal expansion of hair is the same as that of brass. No allowance has been made in computing the published figures for the fact that the results of the calibration are not considered to be valid at low temperatures below the freezing point.

Data of well marked inversions and regions of zero lapse rate in the troposphere are included in the notes on the soundings. They are set out in a uniform manner on the principle that corresponding values of height, temperature and relative humidity are given for the salient points in each special case, the sequence being always from lesser heights to greater.

The figures given in the table of lapse rates do not in every case agree with the temperatures appearing in the table of temperature-heights. The reason for this is that both were determined independently from the original data, which can sometimes profitably be read to the nearest half degree, but are rounded off to whole degrees for publication.

The lapse rates given between ground level and 0·5 Km. are determined from the reading in the thermometer screen at the station and that of the meteorograph at 0·5 Km. A source of error arises here in that the two standards are independent and are not exposed in the same manner. A small difference is capable of making an appreciable error in the lapse rate, and it is possible that lapse rates apparently greater than 10a. per Km. in this layer are sometimes due to this cause.

Whenever possible the meteorograph was calibrated again after return before the record plate had been disturbed, in order to discover whether any shift of zero had taken place since the previous calibration. Some disturbance is almost inevitable considering the rough treatment experienced, more especially in the shock of the fall. It is satisfactory to note that for the year 1929, omitting one case in which very large shifts of zero had taken place, the mean values of the shifts taken without regard to sign were small, being 2·7 mb. for the pressure and 1·0 a. for the temperature.

All new meteorographs, and all old ones used again after repair, were seasoned in a vacuum chamber before use by being subjected to several slow reductions of pressure. This process has been found greatly to reduce the chance of a systematic difference occurring between the results of a fast and slow calibration. More detail is given in the Introduction to the tables for 1923, and within the limits of accuracy at present attainable in the measurement of upper air pressures, the results of the fast reduction of pressure in the calibration test may be taken as applying to the slow reduction in the actual sounding.

The lag, or difference in pressure reading as between a falling and a rising pressure, is of the order 3 or 4 millibars on the average in the middle region of a high sounding, falling off to lesser values on either side. If a correction be applied to the recorded temperature-pressures to allow for this error, it results, for an average sounding in the troposphere, in an increase in the difference between the temperatures recorded at any pressure on the ascent and descent. The effect is to make the recorded temperatures on the descent too high by about half a degree at a height of 6 or 7 kilometres, with a tendency for the error to fall off above and below. When the mean of the two records is employed the resultant error is halved and becomes negligible.

In Table 547 occur the entries "Type of Tropopause" and "H_c = Height of Tropopause." These are defined as follows:—Type I. The stratosphere commences with an inversion, and H_c is the height of the first point of zero temperature gradient. Type II. The stratosphere begins with an abrupt transition to a temperature gradient below 2a. per kilometre without inversion, and H_c is the height of the abrupt transition. Type III. There is no abrupt change of temperature gradient, and the base of the stratosphere is taken at the point where the mean fall of temperature for the kilometre next above is 2a. or less, provided that it does not exceed 2a. for any subsequent kilometre. In the Remarks on the Soundings the pressure distribution is classified according to the types defined in "Aids to Forecasting."†

†—E. Gold, F.R.S., Geophysical Memoir No. 16, M.O. 220f, London, 1920.

Some statistical results of the soundings made in England during the nine years 1921-29 are set out below. The data include that which was employed in the formation of the results given on Page 364 of the *Observatories' Year Book*, 1925.

Means and correlation coefficients are given based on 223 soundings, of which about 60% were made from Sealand Aerodrome, 20% from Benson and 20% from Kew Observatory. Mean temperatures are given for each season, winter indicating the three months Dec.-Jan.-Feb. and so on. In the determination of the correlation coefficients the seasonal variations have been ignored and all departures taken from the annual means.

548. 1929.

REMARKS ON THE SOUNDINGS AND THE PREVAILING WEATHER CONDITIONS, 1929.

No. of Ascent.

722. Weather fair. Clouds St-Cu. 7/10 from N. at about 1·3 Km. Inversion on ascending record from 1·3 Km. to 1·55 Km., temperature 268a. to 271·5a., relative humidity 92% to 83%. Inversion on descending record from 1·19 Km. to 1·28 Km., temperature 270a. to 272a., Isothermal layer from 2·14 Km. to 2·77 Km., temperature 270a., relative humidity 76% to 36%. Pressure distribution :—Ridge of high pressure extending across the British Isles from an anticyclone over Greenland to Central Europe, low pressure areas over Scandinavia and in mid Atlantic. Type I.

725. Weather overcast. Clouds St. 10/10 at about 0·3 Km. The balloon did not burst and floated at the greatest height with a rise of temperature of 12A., which was ignored. Many small oscillations of temperature appear on both records near the top, especially on the ascent with amplitudes up to ±1a. Inversions from 0·39 Km. to 0·68 Km., temperature 275a. to 277·5a., relative humidity 100% to 77%. Pressure distribution :—Pressure high over Greenland, Scandinavia, and The Azores. Small depressions NE. of Iceland, over France and in advance of a large depression to the west of Ireland. Type VIIb.

726. Weather overcast with fog. Clouds St. 10/10 from SE. at about 0·1 Km. Inversions from 0·26 Km. to 0·44 Km., temperature 275a. to 279a., relative humidity —to 62%, and from 2·76 Km. to 3·03 Km., temperature 267a. to 268a., relative humidity 77% to 44%. Pressure distribution :—Large anticyclone covering Europe and Eastern England moving SE. Large depression moving NE. from the Atlantic. Small lows developing over Scandinavia. Type VIa.

727. Weather cloudy with slight rain. Clouds St. and St-Cu. 10/10 from SW. at about 0·3 Km. The balloon floated at the highest point with rise of temperature due to insolation, the results from this region have therefore not been tabulated. Inversion on descending record from 1·37 Km. to 1·53 Km., temperature 278a. to 279·5a. Pressure distribution :—Depression to the north of the British Isles, passing NE., high pressure over Central Europe and over Greenland. Shallow trough of low pressure north of the Azores. Type VI.

728. Weather fine. Clouds Ci. 3/10 from W. by S. Balloon did not burst and floated at the highest point, causing a rise of temperature of 3a. which has been ignored. Small inversion on ascending record from 0·56 Km. to 0·85 Km., temperature 281a. to 282a., relative humidity 51% to 28%. Pressure distribution :—Deep depression over Scandinavia with a secondary moving across Scotland. A further depression moving NE. from The Azores, continental anticyclone withdrawing slowly. Type IVa.

729. Weather fine. Clouds Ci. 3/10 from W. The large lapse rate near the surface appears to be genuine as it is also shown on the record itself between 0·24 Km. and 0·50 Km. Inversion from 2·48 Km. to 2·85 Km., temperature 261a. to 262a., relative humidity 34% to 29%. Isothermal layer from 4·13 Km. to 4·91 Km., temperature 255a., relative humidity 17% to 14%. Pressure distribution :—A large anticyclone moving in over the British Isles from the Atlantic, depressions over Scandinavia and the Bay of Biscay. Type XIa.

730. Weather fair. Clouds Cu. and Fr-Cu. 5/10 at about 1Km. An automatic release was employed to limit the sounding. The large lapse rate near the surface was confirmed by the fog balloon sent up about an hour previously. Pressure distribution :—A belt of high pressure moving slowly eastwards over the British Isles. A depression west of the Azores moving very slowly NE. Pressure low generally over Scandinavia and Central Europe. Type IX.

731. Weather cloudy. Clouds St-Cu. 10/10 from N. by E. at about 0·7 Km. Inversion from 1·46 Km. to 1·66 Km., temperature 275·5a. to 280·5a. Pressure distribution :—A large anticyclone centred to the north of the British Isles. Low pressure areas over Scandinavia and the Mediterranean. Type IX.

733. Weather fair. Clouds A-Cu. 1/10, Ci-Cu. 5/10. Ci-Cu. travelling slowly from S. Small lapse rate of 1·6a. per Km. below base of stratosphere from 11·5 Km. to 12·3 Km. Pressure distribution :—High over France, large depression to the north east of Iceland, a secondary depression moving NE. across Scotland. Type XIa.

547. T.=Temperature in Degrees absolute. P.=Pressure in millibars. H.=Height in kilometres above M.S.L. RH.=Relative Humidity as percentage. 1929.

548. 1929.

REMARKS ON THE SOUNDINGS AND THE PREVAILING WEATHER CONDITIONS, 1929.

No. of Ascent.

734. Weather cloudless. The balloon floated at the highest point, the rise of temperature shown on the record was ignored. Isothermal layer from 0·58 Km. to 1·00 Km., temperature 291a. Pressure distribution :—An anticyclone over the North Sea decreasing before the advance of a depression south-west of Ireland. Type VIIa.

735. Weather fair. Clouds Cu. 4/10 from SW. at about 1·3 Km., A-Cu. 1/10 from SW. by S. In tabulating the temperature a slight bias was made towards the ascending record from 1 Km. downwards. The tabulated lapse rate near the surface is probably slightly too large owing to the fact that the temperature at 0·5 Km. was deduced from both the ascending and descending records. The visible part of the ascending record itself, however, shows a lapse rate of 10·5a. per Km. from 0·16 Km. upwards. Isothermal layer from 1·44 Km. to 1·77 Km., temperature 282a., relative humidity 83% to 62%. Pressure distribution :—A depression moving north-east over Scotland and Northern England, pressure, high over the Channel and Central Europe. Type IV.

737. Weather fair. Clouds Cu. and Ci. 6/10, Cu. from WNW. at about 0·8 Km., Ci. from WNW. Pressure distribution :—An anticyclone situated to the south-west of the British Isles, where pressure is rising slowly. A depression over Scandinavia. Type XIa.

738. Weather cloudy. Clouds St-Cu. 5/10 from SW. at about 1·5 Km., A-Cu. 3/10 from W. A rise in temperature at the highest point was ignored and a bias was made towards the descending record above 15 Km. Inversion from 2·06 Km. to 2·33 Km., temperature 273·5a. to 275.5a., relative humidity 96% to 61%, another on the ascending record only from 4·09 Km. to 4·25 Km., temperature 264·4a. to 267a., relative humidity 96% to 66%, on the descending record from 3·90 Km. to 4·04 Km., temperature 265a. to 267a. Pressure distribution :—A trough of low pressure extending from Iceland to the west of Ireland is moving eastwards, an anticyclone extends over Central Europe, and the English Channel. Type VIa.

739. Weather fair. Clouds St. 2/10 from WNW. at about 0·6 Km., Ci. and Ci-Cu. 5/10 from SW'W. Inversion from 1·56 Km. to 1·96 Km., temperature 274·5a. to 276a., relative humidity 95% to 47%. Pressure distribution :—A trough of low pressure extending from Iceland to the North Sea moving eastwards while a ridge of high pressure follows from the Atlantic. Type XII.

740. Weather fine. Clouds Cu. and St-Cu. 1/10, Ci. and Ci-St. 2/10. Cu. from west at about 0·8 Km., St-Cu. from WSW. at about 2·2 Km., Ci. from WSW. Inversion on the ascending record from 2·17 Km. to 2·39 Km., temperature 271·5a. to 274a., relative humidity 80% to 46%, inversion on the descending record from 2·35 Km. to 2·55 Km., temperature 269a. to 272·5a. Pressure distribution :—A shallow depression lies to the north of the British Isles and an anticyclone to the south-west, a small secondary is indicated to the west of Ireland. Type XIa.

743. Weather cloudy. Clouds St. 5/10, Cu. 5/10. An automatic release was employed to limit the sounding. Pressure distribution :—A large depression situated between Iceland and Scandinavia moving north-east. Pressure high to the south-west of the British Isles. Secondaries over the North Sea. Type II.

744. Weather fair. Clouds Fr-Cu. 2/10 from SSW., Ci. 2/10 nearly stationary. Two meteorographs were sent up together in one frame and the tabulated records are mean results of the two. The large lapse rate below 0·5 Km. may be partly due to the wide separation of the ascending and descending records at 0·5 Km. and possibly also the screen temperature may have read too high on a fine afternoon with light wind. Pressure distribution :—A deep depression situated to the north-east of Iceland is connected with a secondary over the English Channel by a shallow trough. Pressure high to the south-west and over Eastern Europe. Type XII.

745. Weather cloudy. Clouds St-Cu. 8/10, A-Cu. 1/10, A-Cu. nearly stationary. Two meteorographs were employed, the tabulated figures being derived from the mean results of the two. The mean of both ascending and descending records was used in forming the temperature tables, except below 0·9 Km. where the ascending record only was employed. Inversion from 1·02 Km. to 1·25 Km., temperature 285·5a. to 286·5a., relative humidity 93% to 78%, another inversion on descending record from 4·43 Km. to 4·56 Km., temperature 263·5a. to 264·5a. Pressure distribution :—A very deep depression over Iceland with secondaries over the British Isles. Pressure high to the south-west. Type XIa.

548. 1929.

No. of Ascent. REMARKS ON THE SOUNDINGS AND THE PREVAILING WEATHER CONDITIONS, 1929.

746. Weather cloudy. Clouds St-Cu. and St. 10/10 at about 0·8 Km. Two Meteorographs were used and their records agreed well, the published figures being in general derived from the mean of the two. Very large lapse rate shown in the stratosphere :—4a. per Km. from 13·2 Km. to 14·1 Km. Inversions on ascending record from 1·66 Km. to 2·10 Km., temperature 278a. to 279a., relative humidity 96% to 94% ; from 3·26 Km. to 3·42 Km., temperature 273a. to 274a., relative humidity 95% to 89% ; from 4·23 Km. to 4·45 Km., temperature 268·2a. to 269·5a., relative humidity 75% to 50%. Inversions on descending record from 1·00 Km. to 1·20 Km., temperature 279·5a. to 282·0a. ; from 4·04 Km. to 4·24 Km., temperature 267·2a. to 269·7a. Isothermal on descending record from 1·75 Km. to 2·10 Km., temperature 279a. Pressure distribution :—A depression between Iceland and Scandinavia, moving east ; a large anticyclone situated to the south-west of the British Isles. Type XII.

747. Weather fair and slight mist. Clouds Ci. 6/10 from SW. Isothermal layer from 1·25 Km. to 1·63 Km., temperature 273a., relative humidity 61% to 35%. Pressure distribution :—A secondary depression over the northern half of the British Isles, an anticyclone over Central Europe. Type V.

748. Weather cloudy. Clouds St. 6/10 ; Fr-Cu. 2/10 ; A-Cu. 1/10 moving very slowly. Isothermal layer from 1·30 Km. to 1·62 Km., temperature 275·5a. Inversion from 2·00 Km. to 2·30 Km., temperature 272·5a. to 274a. Isothermal layer from 2·88 Km. to 3·5 Km., temperature 269a. Pressure distribution :—An anticyclone centred over the Azores and a large depression moving eastwards along the Arctic Circle. Type Ia.

749. Weather cloudy. Clouds St. and St-Cu. 10/10 at about 1 Km. Two meteorographs were used and the mean of both records was employed throughout. The balloon did not burst, a rise in temperature at the top was assumed to be due to insolation and was ignored. Inversion from 2·0 Km. to 2·1 Km., temperature 268·5a. to 274a., relative humidity 97% to 68%. Pressure distribution :—The same as in the case of No. 748. Type Ia.

750. Weather cloudy. Clouds St. 10/10 from SSW. at about 0·3 Km. Inversion from 1·30 Km. to 1·76 Km., temperature 275·5a. to 276·5a. Pressure distribution :—An intense depression off Northern Ireland is moving rapidly north-east and deepening. Type III.

751. Weather overcast with slight rain. Clouds St. 10/10. from S. at about 0·2 Km. A small rise of temperature at the top was apparently due to insolation and was ignored. Pressure distribution :—A deep and extensive cyclone to the north-west of Ireland moving north-eastwards. Type Va.

753. Weather fair after a shower. Clouds Cu-Nb. and St-Cu. from W. at about 0·6 Km. Large lapse rate in the stratosphere from 223a. at 15·21 Km. to 218a. at 16·38 Km. Pressure distribution :—A deep and extensive cyclone with centres over the North Sea and South East Iceland moving north-eastwards. Type IV.

754. Weather fair after a slight shower. Clouds Cu-Nb. and St.-Cu. 4/10 from W. at about 0·6 Km. Small isothermal from 5·91 Km. to 6·05 Km., temperature 233·5a., relative humidity 69% to 65%. Pressure distribution :—A depression centred between Iceland and Norway has a secondary centre over the North Sea and is moving eastwards. Type II.

756. Weather cloudy. Clouds St., St-Cu. and Ci. 8/10 ; St-Cu. from W. by S. at about 1·5 Km., Ci. from W. Inversion near surface on descending record, upper limit at 0·75 Km., temperature 285a. Small inversion on ascending record from 3·25 Km. to 3·40 Km., temperature 266·5a. to 267a., relative humidity 87% to 53%. Pressure distribution :—A depression with its centre to the north-west of Scotland moving eastward. Pressure high over Europe. Type V.

548. 1929.

No. of Ascent. REMARKS ON THE SOUNDINGS AND THE PREVAILING WEATHER CONDITIONS, 1929.

757. Weather fine. Clouds St-Cu. 1/10 from NW. at about 1·3 Km. Inversion near ground on descending record. Inversion on ascending record from 1·22 Km. to 1·30 Km., temperature 269a. to 272a., relative humidity 25%. Inversion from 3·65 Km. to 3·84 Km., temperature 254a. to 255a., relative humidity 26%. Pressure distribution :—A large anticyclone centred off the south-west coasts of the British Isles, moving slowly eastwards. Type VIIIb.

758. Weather fair. Clouds A-St. 3/10, Ci-St. 2/10 slowly from NW. Inversion near ground. Inversion from 1·20 Km. to 1·50 Km., temperature 270a. to 273a., relative humidity 69% to 54%. Isothermal layer from 1·75 Km. to 2·31 Km., temperature 272a., relative humidity 38% to 21%. Pressure distribution :—An intense anticyclone over the Channel is moving slowly eastwards. Type XI.

759. Weather fine. Clouds St-Cu. 2/10 slowly from SW. at about 1·3 Km. Inversion near ground : inversion from 1·33 Km. to 1·61 Km., temperature 271a. to 273a., relative humidity 83% to 63%. Inversion on descending record from 2·99 Km. to 3·21 Km., temperature 265a. to 265·5a. Pressure distribution :—A large anticyclone with centres over South-east England and over Germany is moving slowly eastwards. Type XI.

760. Weather cloudy. Clouds St-Cu. 9/10 from SW. at about 1·3 Km. Inversions from 1·43 Km. to 1·48 Km., temperature 271a. to 274a., relative humidity 100% ; and from 1·97 Km. to 2·25 Km., temperature 272·5a. to 274·0a., relative humidity 80% to 61%. Pressure distribution :—A large anticyclone centred over Germany. Type VIa.

761. Weather cloudless with slight mist. Very small lapse rate between the ground and 2·3 Km. Inversions from 1·00 Km. to 1·19 Km., temperature 274·5a. to 276·0a., relative humidity 43% to 36% ; on ascending record only from 5·94 Km. to 6·03 Km., temperature 246a. to 247·5a., relative humidity 36% to 35%. Inversion on descending record from 5·55 Km. to 5·86 Km., temperature 247·5a. to 248a. Pressure distribution :—Anticyclone over Germany, trough of low pressure off the west of Ireland. Type VIa.

762. Weather cloudless. Inversions near ground ; from 1·35 Km. to 1·84 Km., temperature 272a. to 273a. ; from 4·53 Km. to 4·76 Km., temperature 255·5a. to 258a. Small isothermal layer from 11·33 Km. to 11·67 Km., temperature 206·5a. Pressure distribution :—A trough of low pressure moving eastwards across the British Isles, pressure high over Germany. Type Va.

763. Weather fair. Clouds St-Cu. 2/10, A-Cu. and Ci 4/10 ; St-Cu from WSW. at about 1·1 Km., Ci. from WSW. Small inversion on descending record from 1·04 Km. to 1·31 Km., temperature 269·5a. to 270a. Isothermal layer on both records 2·54 Km. to 3·00 Km., temperature 262·5a., relative humidity 71% to 46%. Pressure distribution :—Large depression centred to the south of Iceland, secondaries developing off the west and south-west coasts of the British Isles. Type Va.

766. Weather dull. Clouds St. 10/10. Small isothermal layer at about 5·3 Km., temperature 253a. Pressure distribution :—A deep depression centred to the north-west of Ireland, secondaries crossing the British Isles from the west. Type Va.

768. Weather fine. Clouds Cu. 2/10 from NW. by W. at about 0·6 Km. Inversion in stratosphere from 8·36 Km. to 9·27 Km., temperature 220·7a. to 223·3a. Pressure distribution :—Wedge of high pressure moving eastwards across the British Isles. Type IV.

Abridged List of Publications published by the Authority of the Meteorological Committee

2. JOURNALS

Marine Observer. From January, 1924, in substitution for the monthly issues of Meteorological Charts of the North Atlantic Ocean and East Indian Seas. (No. 262.) (12¼ in. by 9¾ in.) Published monthly. 2s. Postage 2d.
(*Annual subscription, 25s. post free.*)

Meteorological Magazine. Symons's Meteorological Magazine, incorporated with the Meteorological Office Circular. (8vo.) Published monthly. 6d. Postage ½d.
(*Annual subscription, from February to January, 6s. 6d. post free.*)

3. PUBLICATIONS OF DATA (CURRENT PERIODICAL ISSUES)

British Colonies and Protectorates. Notes on Meteorological Observations made in. From 1923. (Fcp.) (*Not on sale.*)

British Rainfall. (8vo.) A Report upon the progress of Rainfall Investigations and full records of the Rainfall of each year, with Maps and Illustrations :—
1865 to 1879, each 5s.
1880 to 1918, each 10s.
1919 to 1921, each 12s. 6d.
1922 to 1929, each 15s.
(Volumes for 1876, 1881, 1911, 1917 and 1918, *out of print.*)

Daily Weather Report. 1. British Section. (12½ in. × 13 in.) 2. International Section. (4to.) 3. Upper Air Section. (4to.) Subscription 13s. post free per official quarter for two or three sections, 6s. 6d. per official quarter for one section. Single copies, price 1d. each.

Orders or correspondence should be addressed to the Director, Meteorological Office, Air Ministry, Kingsway, London, W.C.2. Cheques and Postal Orders should be made payable to the "Secretary, Air Ministry," and crossed "Bank of England, a/c of H.M. Paymaster-General."

Monthly Frequency Tables from January, 1927. (Fcp.) Summaries of observations of horizontal visibility, height of base of low cloud and speed and direction of surface and upper winds in the form approved by the International Commission for Air Navigation. (*Not on sale.*)

Monthly Weather Report. (4to.) The publication of the Monthly Weather Report began in 1884. After 1887 it was published as a Supplement to the Weekly Weather Report, and formed Part II of the British Meteorological and Magnetic Year Book from 1908 to 1921. Contains summaries of Observations from about 330 Stations in the British Isles, and Charts. Monthly Parts and Annual Summary, each 1s. Postage ½d.
(*Annual subscription, including Introduction and Annual Summary, 15s. post free.*)

Observatories' Year Book, commencing 1922. (4to.) In continuation of Parts III (2) and IV of the British Meteorological and Magnetic Year Book. Volumes for 1922 and 1923, each 63s.; 1924, 57s. 6d.; 1925 to 1928, each 63s.

Réseau Mondial. (4to.) Monthly and Annual Summaries of Pressure, Temperature and Precipitation based on a World-Wide Network of Observing Stations. Commencing 1910 :—
Charts.—1910, 8s. 6d.; 1911, 3s. 6d.
Tables.—1910, 15s.; 1911 to 1913, each, 7s. 6d.; 1914, 18s.; 1915, 24s.; 1916, 22s. 6d.; 1917, 22s. 6d.; 1918, 21s.; 1919, 22s. 6d.; 1920, 24s.; 1921, 24s.; 1922 and 1923, each 25s.

Weekly Weather Report. (4to.) Published in weekly numbers from February, 1878, to February 25, 1928 (at prices ranging from 2d. to 9d. each), and thereafter in annual volumes referring to the Seasonal Year (i.e., from the beginning of Spring to the end of Winter) Volumes for 1928–9 and 1929–30, each 15s.

4. PUBLICATIONS OF NORMALS OR AVERAGES

Average Monthly Rainfall of the British Isles, 1881 to 1915. By M. de C. S. Salter. (*Reprinted from* British Rainfall, 1920.) (8vo.) 6d. Postage 1d.

Diurnal Range of Rain at the Seven Observatories in connection with the Meteorological Office. 1871–90. (No. 143. 1900.) (8vo.) 2s. 6d. Postage 1d.

4. PUBLICATIONS OF NORMALS OR AVERAGES—*contd.*

Normals of Meteorological Elements for the British Isles. Book of. (No. 236.) (8vo.) :—

Section I. Monthly Normals of Temperature, Rainfall and Sunshine for Stations. 2s. Postage 1½d.

Section II. Normals, Weekly, Monthly, Quarterly and Seasonal for Districts. 9d. Postage ½d.

Section III. Maps of the Normal Distribution of Temperature, Rainfall and Sunshine. 1s. 6d. Postage 1d.

Section IV. (*a*) Range of Variation of Temperature and Rainfall; (*b*) Frequency Tables for Hail, Thunder, Snow, Snow Lying and Ground Frost. 3s. 6d. Postage 1d.

Section V. Monthly Normals of Rainfall. 4s. Postage 1d.

Section VI. Normals of Relative Humidity. 9d. Postage 1d.

Rainfall for the London District, comprising (1) Serial Monthly Totals for the Century 1813–1912; and (2) Daily, Five Daily and Monthly Normals. (No. 219. 1913 and 1916.) Two Charts (each 33½ in. by 26 in.). Each 6d.

Rainfall Tables of the British Isles for 1866–80. Compiled by G. J. Symons, F.R.S. (No. 47. 1883.) (8vo.) 7s. 6d. Postage 3d.

Rainfall Tables of the British Islands. 1866–90. (No. 114. 1897.) (8vo.) 6s. Postage 4d.

Temperature Tables for the British Islands. (No. 154. 1902.) (4to.) 10s. 6d. Postage 5d.
Supplement. Difference Tables for each Five Years for the Extrapolation of Mean Values. 3s. Postage 1½d.

Ten Years' Sunshine in the British Isles. 1881–90. (No. 98. 1891.) (8vo.) 2s. Postage 1½d.

6. PUBLICATIONS OF RESEARCHES

Barometric Gradient and Wind Force. Report to the Director of the Meteorological Office by E. Gold, M.A., Fellow of St. John's College, Cambridge, Superintendent of Instruments. (No. 190. 1908.) (4to.) 2s. 6d. Postage 2½d.

Free Atmosphere in the Region of the British Isles. First Report by W. H. Dines, F.R.S., with an introduction and Note on the Perturbations of the Stratosphere by W. N. Shaw, Sc.D., F.R.S., Director. (No. 202. 1909.) (4to.) 2s. 6d. Postage 2½d.

Gales experienced in the Ocean District adjacent to the Cape of Good Hope, between Lat. 30° and 50° S., and Long. 10° and 40° E. Report on. By Capt. H. Toynbee, F.R.A.S. (No. 44. 1882.) (4to.) 7s. 6d. Postage 6d.

London Fog Inquiry. 1901–03 :—
Report of the Meteorological Council, with Report by R. G. K. Lempfert, M.A. (No. 160. 1904.) (4to.) 2s. 6d. Postage 2½d.
Report by Capt. Alfred Carpenter, R.N., D.S.O. (1903.) (4to.) 2s. Postage 2d.

Relation between Pressure, Temperature and Air Circulation over the South Atlantic Ocean. By M. W. Campbell Hepworth, C.B., R.D., Captain R.N.R., Marine Superintendent. (No. 177. 2nd edition, 1917.) (8vo.) 1s. Postage 1d.

"Scotia" s.s. Report to the Board of Trade on the work carried out, 1913. Ice Observation, Meteorology and Oceanography in the North Atlantic Ocean. (1914.) (Fcp.) 4s. 6d. Postage 3½d.
Maps, Charts and Diagrams to illustrate the Report. (1914.) (Fcp.) 2s. 6d. Postage 3½d.

Trade Winds of the Atlantic Ocean. By M. W. Campbell Hepworth, C.B., Commander, R.N.R., J. S. Dines, B.A., and E. Gold, M.A. (No. 203. 1910.) (4to.) 3s. Postage 3½d.

Wind Structure. Reports on. (8vo.) From reports of the Aeronautical Research Committee. (*Nos. 1, 2 and 3 are out of print as separate copies.*) Fourth Report 1912–13. 1s. 6d. Postage 2d.

Abridged List of Publications published by the Authority of the Meteorological Committee

6. PUBLICATIONS OF RESEARCHES—*contd.*

GEOPHYSICAL MEMOIRS. (4to.) :—

Vol. V :—

41. **Influence of Arctic Ice on the Subsequent Distribution of Pressure over the Eastern North Atlantic and Western Europe.** By C. E. P. Brooks, D.Sc. and Winifred A. Quennell. (No. 307a. 1928.) 2s. 6d. Postage 2d.

42. **The Time Interval between Magnetic Disturbance and Associated Sunspot Changes.** By J. M. Stagg, M.A., B.Sc. (No. 307b. 1928.) 1s. Postage 1d.

43. **Regular Diurnal Variation of Magnetic Declination at** Kew Observatory from selected years of Many and Few Sunspots 1859–1894. By C. Chree, Sc.D., LL.D., F.R.S. (No. 307c. 1928.) 2s. 6d. Postage 1d.

44. **Distribution of Mean Annual Maxima and Minima of Temperature over the Globe.** By C. E. P. Brooks, D.Sc., and Miss G. L. Thorman, B.Sc. (No. 307d. 1928.) 1s. Postage 1d.

45. **Measurements of the Effective Electrical Conductivity** of the Air and the Earth's Electric Field at and near ground level by means of the Wilson Universal Electrometer. By R. E. Watson, Ph.D. (No. 307e. 1929.) 2s. Postage 2d.

46. **A Study of the Vertical Gradient of Temperature in the Atmosphere near the ground.** By N. K. Johnson, M.Sc., A.R.C.S. (No. 307f. 1929.) 3s. 6d. Postage 3d.

47. **Report on Thames Floods.** By A. T. Doodson, D.Sc., Tidal Institute, University of Liverpool.
Meteorological Conditions Associated with High Tides in the Thames. By J. S. Dines, M.A., Superintendent, Forecast Division, Meteorological Office. (No. 307g. 1929.) 2s. 6d. Postage 2d.

48. **Meteorological Results of Journeys in the Southern Sahara, 1922 and 1927, made by Francis Rennell Rodd, F.R.G.S.** Discussed by C. E. P. Brooks, D.Sc., and S. T. A. Mirrlees, M.A. (No. 307h. 1929.) 3s. 6d. Postage 2d.

49. **Two Notes on the Operation of Galitzin Seismographs.** By F. J. Scrase, M.A., B.Sc. (No. 307i. 1930.) 1s. Postage 1d.

50. **Practical Examples of Polar-Front Analysis** over the British Isles in 1925–6. By J. Bjerknes, D.Ph. (No. 307j. 1930.) 3s. Postage 3d.

Vol. VI :—

51. **A Study of Visibility and Fog at Malta.** By J. Wadsworth, M.A. (No. 331a. 1930.) 1s. 6d. Postage 2d.

52. **Some Characteristics of Eddy Motion in the Atmosphere.** By F. J. Scrase, M.A., B.Sc. (No. 331b. 1930). 1s. 6d. Postage 2d.

PROFESSIONAL NOTES. (8vo.) :—

Vol. IV :—

47. **Regression Equations with many Variates.** By C. E. P. Brooks, D.Sc. (No. 273g. 1927.) 3d. Postage ½d.

48. **Falling Time of Marine Barometers.** Historical Note and some recent observations. By E. Gold, F.R.S. (No. 273h. 1928.) 3d. Postage ½d.

49. **Sunspots and the Distribution of Pressure over Western Europe.** By C. E. P. Brooks, D.Sc. (No. 273i. 1928.) 3d. Postage ½d.

50. **Some Regions of Formation of Depressions in the North Atlantic.** By L. Doris Sawyer, B.A. (No. 273j. 1928.) 4d. Postage 1d.

51. **Changes of Zero in Spirit Thermometers.** By W. F. Higgins, M.Sc., Physics Department, National Physical Laboratory and E. G. Bilham, B.Sc., A.R.C.Sc., D.I.C., Superintendent of Instruments, Meteorological Office, (No. 273k. 1929.) 4d. Postage ½d.

52. **Bumpiness on the Cairo-Basra Air Route.** By J. Durward, M.A. (No. 273l. 1929.) 3d. Postage ½d.

53. **Relation between the Duration of Bright Sunshine Registered by a Campbell-Stokes Sunshine Recorder and the Estimated Amount of Cloud.** By C. E. P. Brooks, D.Sc. (No. 273m. 1929.) 9d. Postage 1d.

6. PUBLICATIONS OF RESEARCHES—*contd.*

PROFESSIONAL NOTES—*contd.*

54. **Variations of Pressure Distribution in the Northern Hemisphere** during the period 1904–1913, based on 10-day means. By C. E. P. Brooks, D.Sc., and Winifred A. Quennell. (No. 273n. 1929.) 9d. Postage 1d.

55. **Report on the Observations of Terrestrial Magnetism made in the British Isles on the occasion of the Total Solar Eclipse of 29th June, 1927.** By H. W. L. Absalom, B.Sc. (No. 273o. 1930.) 9d. Postage 1d.

56. **Auroral Observations at Lerwick Observatory, 1924–9.** By A. W. Lee, M.Sc. (No. 273p. 1930.) 3d. Postage ½d.

57. **The Effect of Variation in Relative Wind Force on the Readings of the Wet and Dry Bulb Thermometers in a Portable Screen on Board Ship.** By E. G. Bilham, B.Sc., D.I.C., and J. E. Belasco, B.Sc. (No. 273q. 1930.) 3d. Postage ½d.

58. **A New Relation between Atmospheric Electricity and Terrestrial Magnetism.** By. A. W. Lee, M.Sc., D.I.C. (No. 273r. 1930.) 3d. Postage ½d.

59. **Some Observations of Upper Air Temperature in Iraq.** By S. P. Peters, B.Sc. (No. 273s. 1930). 3d. Postage ½d.

60. **Weather Conditions over the Central and Western Mediterranean** during the period February 10-14, 1929. By G. A. Bull, B.Sc. (No. 273t. 1931) 6d. Postage 1d.

Vol. V :—

61. **A Comparison of Temperatures Inside and Outside the Meteorological Enclosure at the Airship Base, Ismailia, Egypt.** By J. Durward, M.A. (No. 336a. 1931.) 2d. Postage ½d.

7. ANNUAL REPORTS OF THE METEOROLOGICAL OFFICE (8vo.) :—

1867–1920, at prices ranging from 1d. to 2s. 3d., except 1876–77, 3s. 5d., and 1884–85, 4s. 4d. (1867–73, 1903–04 and 1907–10, *out of print.*)
1920–21, 2s. Postage 1d.
1921–22 (No. 257), 2s. Postage 1d.
1922–23 (No. 258), 1s. 6d. Postage 1d.
1923–24 (No. 267), 1s. 6d. Postage 1d.
1924–25 (No. 274), 1s. 9d. Postage 1d.
1925–26 (No. 288), 2s. Postage 1½d.
1926–27 (No. 298), 2s. Postage 1½d.
1927–28 (No. 308), 1s. 6d. Postage 1d.
1928–29 (No. 318), 1s. 6d. Postage 1d.
1929–30 (No. 328), 1s. Postage 1d.

9. REPORTS OF INTERNATIONAL METEOROLOGICAL MEETINGS (8vo.) :—

Reports of Meetings of the International Meteorological Committee and Commissions, 1872 to 1920, at prices ranging from 4d. to 5s.
1921. London. Eleventh Meeting of Committee. (No. 248.) 4s. 6d. Postage 2d.
1921. London. Fourth Meeting of Weather Telegraphy Commission. (*Reprint of* Appendix VI of Report of the Eleventh Meeting of Committee, *see* No. 248.) (No. 251.) 1s. 6d. Postage 1d.
1925. London. Commission for the Exploration of the Upper Air. (No. 281.) 2s. Postage 1½d.
1926. Zürich. Sixth Meeting of Commission for Synoptic Weather Information. (No. 293.) 2s. Postage 1½d.
1926. Zürich. Commissions for Terrestrial Magnetism and Atmospheric Electricity, and for Réseau Mondial. (No. 296.) 9d. Postage ½d.
1927. Leipzig. Commission for Exploration of the Upper Air. (No. 300.) 3s. 6d. Postage 1d.
1928. London. Seventh Meeting of Commission for Synoptic Weather Information. (No. 309.) 6s. 6d. Postage 3d.
